e Estimate. p Preliminary. r Revised.

[1] Table excludes all ferroalloy production except where otherwise noted.

[2] In addition to the countries listed, North Vietnam and Zaire presumably have facilities to produce pig iron, but available information is inadequate to make reliable estimates of output levels.

[3] Includes sponge iron output as follows in thousand short tons: Mexico: 1972—865; 1973—831; 1974—e 990; Sweden: 1972—196; 1973—r 209; 1974—217.

[4] Includes ferroalloys, if any are produced.

[5] May include blast furnace ferroalloys for 1973 and 1974.

[6] May include ferroalloys.

[7] Includes blast furnace ferroalloys except ferromanganese, ferrosilicon and spiegeleisen.

[8] Includes blast furnace ferroalloys, if any are produced.

[9] Includes ferroalloy production.

[10] Revised to zero.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Steel formed in first solid state after melting suitable for further processing or sale.

[2] In addition to the countries listed, North Vietnam produces raw steel, but information is inadequate to make reliable estimates of output levels.

[3] Data from American Iron and Steel Institute (AISI). Excludes steel produced by foundries not reporting output to AISI but reported to Bureau of Census as follows (in thousand tons): 1972—[r] 1,584; 1973—[r] 1,894; 1974—2,092.

[4] Ingots only.

[5] Apparently excludes shipyards' production of steel castings.

Iron and Steel Scrap

By D. H. Desy [1]

In compiling the annual scrap and pig iron statistics for 1974 (but not the monthly statistics as published in Mineral Industry Surveys), an augmented survey of iron and steel foundries was used. This resulted in apparent increases in scrap consumption of 3.4% for steel foundries, 16.3% for iron foundries and miscellaneous manufacturers, and 3.0% for the total of all types of manufacturers. (A comparison of the totals obtained from the previously used panel compared with those from the augmented panel, which will henceforth be used, is shown in tables 2 and 3.) Domestic consumption of iron and steel scrap in 1974 fell by 1.2%, compared with that of 1973, when both years are compared on the basis of the unaugmented survey. Continuing high domestic and foreign demand during the first half of 1974 influenced prices to rise to record highs, despite the imposition of export controls during the year.

Direct-reduced iron (prereduced iron) was utilized by a few steel companies for electric furnace steel production. Total consumption of direct-reduced iron in 1974 was 614,000 tons.

Research in recycling of ferrous waste materials continued in Bureau of Mines laboratories. Increasing amounts of ferrous waste were being made available by municipal recycling centers throughout the country.

Legislation and Government Programs.—Export controls on iron and steel scrap were imposed by the U.S. Department of Commerce throughout the year. Total export quotas of 2.1 million tons per quarter in 1974 were established at the beginning of each quarter. Of this amount, 100,000 tons was reserved for contingencies during the first quarter, and 150,000 tons for contingencies and 50,000 tons for vessels sold by the U.S. Maritime Administration for scrapping abroad for each of the last three quarters. Quotas on all grades of scrap iron and steel except stainless steel scrap were established for individual countries and for exporters according to historical patterns. During the fourth quarter, 480,000 tons of the total quota was set aside for licensing to exporters, without regard to their past history of exports, to provide increased opportunity for participation by all exporters. Export controls were removed December 31, 1974.

Effective February 15, 1974, the Cost of Living Council removed all phase IV price controls on ferrous scrap. These controls had applied to prompt industrial and processed obsolete ferrous scrap handled by firms with sales of more than $50 million per year and with more than 60 employees.

---

Scrap (includes tinplate and terneplate scrap)	349	201
Value	$19,100	$27,027

[r] Revised.

AVAILABLE SUPPLY

The new supply of iron and steel scrap available for consumption at consumers' plants in 1974 was 106.6 million tons. It consisted of 55.3 million tons of home scrap and 51.3 million tons of purchased scrap (net receipts). Because of the change in the reporting panel, these figures cannot be directly compared with those for 1973.

CONSUMPTION

Consumption of iron and steel scrap in 1974 was 105.5 tons. Manufacturers of pig iron, steel ingots, and castings took 81.1 million tons, or 77% of the total. Iron foundries and miscellaneous users consumed 21.1 million tons, or 20%, and manufacturers of steel castings consumed the remainder. Because of the change in the reporting panel, these figures cannot be directly compared with those for 1973.

STOCKS

Consumers' stocks reported on hand as of December 31, 1974, were 8.4 million tons. Because of the change in the reporting panel, this figure cannot be directly compared with that for 1973.

PRICES

Prices for iron and steel scrap reached alltime records in 1974. The Iron Age composite price for No. 1 heavy melting scrap peaked at $144.50 per long ton on April 1, and the average monthly composite price attained its highest point at $127.60 per long ton in July. The average annual composite price for No. 1 heavy melting scrap was $108.52, 87% above the average price of $57.95 for 1973. Prices for other grades of scrap generally reached equivalently high levels. After July, prices generally declined, and the composite price for No. 1 heavy melting scrap was $76.83 per long ton at yearend.

FOREIGN TRADE

Exports of iron and steel scrap (excluding rerolling material, and ships, boats, and other vessels for scrapping) amounted to 8.5 million short tons in 1974, 22% less than the 10.9 million tons exported in 1973, reflecting the imposition of scrap export controls during 1974.

Japan was the largest importer of U.S. scrap, taking 35.1% of the total in 1974. The next largest importers were Canada, Spain, and Mexico, which received 11.1%, 10.5%, and 10.5%, respectively.

No. 1 heavy melting steel scrap continued as the largest export grade, accounting for 30% of the total. Next largest export grades were shredded steel scrap and No. 2 bundles, which accounted for 24% and 15%, respectively.

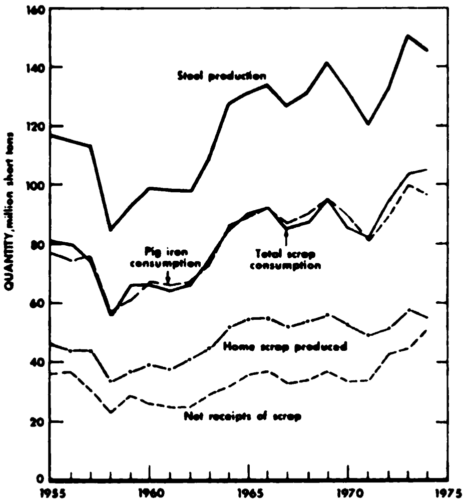

Figure 1.—Steel production (AISI), total iron and steel scrap consumption, pig iron consumption, home scrap production, and net scrap receipts.

WORLD REVIEW

Germany, West.—Demand for scrap remained high as steel production continued to break previous records. Raw steel production was 58.7 million tons, 7% over 1973 production. Total scrap consumption was 28.2 million tons, up 2% from 1973 consumption. Of this amount, 82.1% was used in steel production, 15.7% for gray and malleable iron castings, and 2.2% for pig iron production. Of the total scrap supply of 31.1 million tons, 47% consisted of home scrap, 39% was purchased scrap, and 14% was from other sources and stock adjustments.

India.—Demand for iron and steel scrap in India in 1974 was reportedly 20% below that of previous years, attributed to reduced electric furnace steel production. Between 1969 and 1974, consumption of scrap was less than 1 million tons annually, although the availability of scrap was estimated at about 2.5 million tons annually. Despite the apparent surplus, exports of scrap have been banned since 1969. Scrap processing capacity has remained at about 25% of scrap availability.

Japan.—Japan imported 2.98 million tons of iron and steel scrap from the United States in 1974, 36% less than in 1973, but owing to the higher price of scrap in 1974, the imports were valued at $305 million, compared with $234 million in 1973.

The Steel Scrap Stockpiling Company was formed by nine scrap cartels and will purchase domestic and imported scrap. The purposes are to stabilize the price and supply of scrap. Initially, 275,000 tons will be stockpiled, to be later increased to 1.1 million tons.

Sweden.—There was heavy demand for scrap throughout Scandinavia. The price of scrap in Sweden rose about 38% during the year. Between 60% and 65% of old cars in Sweden are now fragmentized at the Bilfrag plant in Halmstad. Swedish scrap imports for 1974 were estimated at 331,000 tons, mostly from the Soviet Union and Poland. This was a 15% increase over 1973 imports.

United Kingdom.—Exports of ferrous scrap from the United Kingdom in 1974 were 344,000 tons, down from 817,000 tons in 1973 as a result of restrictions on exports during 1974. For most of the year, exports were confined to European Community (EC) countries, and as a result, Spain, formerly the largest importer of United Kingdom scrap, received only 50,000 tons compared with 360,000 tons in 1973. Belgium-Luxembourg was the largest importer with 149,000 tons, and the EC as a whole received 291,000 tons, or 85% of the total. Total imports were 154,000 tons in 1974, down 37% from 245,000 tons in 1973. The transitional period for the United Kingdom's entry into the EC ended December 31, 1974.

TECHNOLOGY

Specialized scrap-handling equipment was increasingly employed by scrap processing firms. About 125 automobile shredders were operating by yearend. The total amount of shredded scrap consumed domestically or exported was 5.2 million tons, up 16% from the equivalent quantity in 1973. Other types of equipment included automobile flatteners, chip briquetters, and engine crushers.

Ferrous scrap was being reclaimed from recycling centers in Houston, Tex., Atlanta, Ga., San Francisco and Oakland, Calif., St. Louis, Mo., Madison, Wis., New Castle County, Del., and several other locations. In all, about 28 centers were operating or in the planning stage. Some of the recycling plant designs were based on the Bureau of Mines raw refuse recycling pilot plant at its College Park (Md.) Metallurgy Research Center.

Small quantities of direct-reduced iron were utilized by some steel plants as a substitute for scrap.

The Bureau of Mines continued its research program on the recycling of waste materials, including ferrous scrap. At the Bureau's Albany (Oreg.) Metallurgy Research Center, research was concluded on continuous charging of electric furnaces with preheated scrap, and mixtures of scrap with prereduced iron pellets. It was found that melting could be done with shorter heat times, lower energy consumption, and higher energy input. A project was also completed that demonstrated the feasibility of producing secondary pig iron from shredded auto scrap. This material would be a suitable substitute for blast furnace pig iron for making gray iron castings.[2] At the Bureau's Rolla (Mo.) Metallurgy Research Center, research was continued on the effects of contaminants such as copper, tin, lead, and chromium in ferrous scrap, originating from municipal waste, on the properties of ductile (nodular) cast iron. The results of studies on the effects of combined tin and copper in as-cast ductile iron were published.[3] Studies continued on the effect of heat treatment on the properties of ductile iron containing minor amounts of copper, tin, and chromium.

In another project at Rolla, chromium, nickel, iron, manganese, and molybdenum were reclaimed from electric furnace flue dusts, mill scale, and grinding swarf.[4] The dusts were pelletized together with a reducing agent and melted in an induction furnace to form an alloy containing 10% to 20% chromium, 6% to 12% nickel, and 55% to 65% iron, plus lesser amounts of manganese and molybdenum.

Metallurgists at the Bureau's Twin Cities (Minn.) Metallurgy Research Center developed a scrap preheating method that uses the hot waste gases generated by the basic oxygen steelmaking process.[5] The method saves up to 44% of the energy required to melt scrap when it is used as part of the charge of the basic oxygen furnace. As a result, the amount of scrap that can be used in this process can be raised from 30% to 40% of the charge.

Also at Twin Cities, it was demonstrated that combinations of automobile scrap and municipal refuse scrap can be successfully converted to gray cast iron in a cupola.[6] Aluminum, in the form of bimetallic cans from municipal refuse, was found to reduce sulfur levels and to improve furnace performance and recovery of silicon in the gray iron produced.

Iron Oxide Pigments

By Thomas S. Jones [1]

Overall levels of production and trade in iron oxide pigments for 1974 remained about the same as those in 1973, although there were shifts for specific oxides. Significant uses were in protective paints for metal and wood, automotive finishes, coil coatings, ferrite manufacture, and coloring of construction materials. Sales and consumption of pigments followed general economic trends; demand remained up until the last quarter, when there was a marked drop. On the plus side were paint trade sales and precoated steel; on the minus side were the housing and construction industries. At the end of 1974, coatings manufacturers were reportedly reducing inventories and maintaining cash flow to raise liquidity. Thus, the apparent adequacy of supply at yearend tended to reflect a short-term decrease in demand rather than an increase in output. This was true for paint raw materials in general, for which the longer term outlook is uncertain. Plans announced for increasing manufacturing capacity for iron oxides should alleviate recent pigment shortages. Oxide prices, especially for synthetics, rose after the expiration of controls.

[r] Revised. W Withheld to avoid disclosing individual company confidential data.

DOMESTIC PRODUCTION

Overall production of crude iron oxide pigments showed an increase of about 5% over that of 1973; specific figures are confidential and cannot be released. Value of shipments rose to $1.4 million, a 53% increase over that of 1973. Production of crude pigments in 1974 was reported by four companies operating in four Midwestern and Eastern States. The Cleveland-Cliffs Iron Co. produced the largest quantity from ore mined in Michigan. Red, yellow (ocher and sienna), black, and brown (umber) oxides were produced from the various mines; one color was produced at each location, except that yellows and browns were both obtained from the same site.

Domestic shipments of finished iron oxide pigments in 1974 were 149,664 short tons, almost the same as those in 1973. Value of shipments increased 39% to $60.3 million, largely as a result of a nearly 50% increase in the average unit value of synthetic oxides, which rose from $0.196 to $0.293 per pound. At $0.075 per pound, the average unit value of natural oxides was virtually unchanged from that of 1973. Synthetic oxides constituted 51% of finished pigments shipments, natural oxides accounted for 43%, and the balance consisted of mixtures and unspecified products. Thus, although the respective tonnages of synthetic and natural pigments did not differ greatly, the value of synthetic pigments was 4 to 5 times that of natural oxides.

---

[1] Physical scientist, Division of Ferrous Metals.

In 1974, 15 companies reported shipments of finished pigments from 20 plants in 11 Eastern and Midwestern States and California. Pfizer Inc. was a major shipper of both synthetic and natural oxides. Cities Service Co., with plants in Missouri and New Jersey, was also a major producer of synthetic oxides. In addition to Pfizer, firms reporting relatively large shipments of natural oxides were Blue Ridge Talc Co., Inc. in Virginia, Delta Color & Supply Co. in Wisconsin, Prince Manufacturing Co. with plants in Illinois and Pennsylvania, and Reichard-Coulston, Inc. in Pennsylvania.

Pfizer completed an expansion of production facilities for synthetic red and yellow oxides at its Emeryville, Calif., plant, and announced plans for adding capacity at three other locations.[2] At East St. Louis, Ill., capacity for production of red oxides was to be doubled and production of yellow oxide was to be increased 40%. At Easton, Pa., capacity for red oxide for magnetic applications was to be enlarged 15,000 tons per year by 1976. A new plant is expected to be completed in 1978 at Sayreville, N.J., for annual production of 12,000 tons of yellow oxide for paint, automotive coating, plastics, and construction materials applications.

BASF Wyandotte Corp. announced plans for a plant at Wyandotte, Mich., for production by mid-1975 of 1,500 tons per year of transparent iron oxides. Trade journals alluded to pending expansions of other companies, along with some difficulty in carrying out planned expansions. Shortly before the end of 1973, Hoover Color Co. of Irvington, N.J., purchased and took over operation of pigment facilities at Hiwassee, Va., formerly owned by Hercules Inc.

CONSUMPTION AND USES

As inferred from data on shipments of finished pigments shown in table 2, the amount and pattern of consumption of iron oxide pigments was much the same in 1974 as it was in 1973. Demand paralleled the state of the economy. Augmented by overseas interest, demand ran equal to or ahead of supply until the fourth quarter; supply was complicated by shortages and the high cost of iron scrap. However, a marked decrease in demand in the fourth quarter kept shipments for the year level with those for 1973. The majority of shipments consisted of red and yellow synthetic oxides and red and brown natural oxides. Use of both natural and synthetic red oxides showed a slight increase, and accounted for nearly half of total consumption. Shipments of brown oxides declined about 15%. Shipments of black oxides shifted from mostly natural grades in 1973 to mostly synthetic grades in 1974. Only small amounts of Venetian red and Vandyke brown were shipped, although several times as much Vandyke brown was imported as was shipped domestically.

Data are not collected by the Bureau of Mines on specific uses for iron oxide pigments. Figures given in table 2 do not necessarily reflect all sales of iron oxides used for pigments and other nonsmelting purposes. Natural and synthetic iron oxides are used for coloring purposes in a wide range of paints, as well as in plastics, rubbers, mortars, concrete, stains, and other products. A major use for both natural and synthetic oxides is metal and wood protection systems. Natural oxides are used particularly in protective coatings for ships, structural steel, freight cars, barns, roofs, and floors. Transparent oxides find use in metallic finishes, especially for automotive, coil, and other decorative coatings. Significant quantities of iron oxide, chiefly synthetic grades, are used to manufacture hard and soft ferrites for magnetic tapes, magnet cores, and other electronic applications. Iron oxides are used in catalysts in the chemical industry. Because of their nontoxic nature, iron oxide pigments are used in cosmetics, drugs, and a number of food applications.

r Revised.
[1] Includes black magnetite and Vandyke brown.
[2] Includes pyrite cinder.
[3] Includes yellow iron oxide.

PRICES

In May, nearly all iron oxide pigments increased significantly in price following the expiration of price controls. The greatest price increase was for synthetic oxides; the price of most colors increased again in the fall, leading to prices at yearend of 60% to 80% above those prevailing at the beginning of 1974. Price increases for natural oxides were less; many colors increased about 40% in price during the year. The prices of metallic brown and raw American sienna rose relatively little (about 10%), whereas domestic ocher did not change in price at all.

Table 3.—Prices quoted on finished iron oxide pigments, per pound, quantity shipments, as of December 30, 1974

FOREIGN TRADE

U.S. exports of pigment-grade iron oxides and hydroxides decreased 2.2% from those of 1973 to 9,666 short tons. However, value rose 11.8% to $3.47 million because of a 14% increase in average unit value to $0.179 per pound. Exports to Canada grew strongly to over three-fourths of total exports, whereas those to Brazil, the United Kingdom, Japan, and Italy dropped sharply.

Imports of iron oxide pigments for consumption grew in 1974 to 54,215 short tons, an increase of 5.9% over the 51,183 short tons imported in 1973. Overall growth in imports was due to increased receipts of synthetic pigments, which rose 12% to 41,943 short tons. Imports of natural pigments decreased 11% to below even the 1972 volume of 12,997 short tons. The value of iron oxide pigment imports increased 36% compared with that of 1973 to $16.4 million. The average unit values showed increases for both synthetic and natural oxide imports of 25% and 20% to $0.179 and $0.057 per pound, respectively.

Synthetic oxides represented 77% of the tonnage and 91% of the value of imports. Receipts from West Germany, Canada, and Japan, in that order, were almost wholly synthetic material, and accounted for 92% of synthetics. Imports of synthetic oxides from West Germany, Japan, and the United Kingdom increased sizably over those in 1973, and more than offset a 25% decrease in Canadian imports. The increase in imports from Japan was particularly notable, nearly 400% at an average unit value only 40% of that for 1973, possibly reflecting a large increase in imports of pigment-grade material. Imports of natural umbers and siennas from Cyprus made that country the third largest import source overall. Shipments reported from Cyprus accounted for 94% of imported umbers and 34% of imported siennas, with the balance of the latter coming from Italy.

Bayer A.-G. in West Germany was reportedly undertaking staged expansion of production capacity for synthetic iron oxide pigments. The first stage was expected to increase production in 1975, and was to be followed by further expansion that would ultimately result in production in 1978 nearly 50% greater than that in 1974. Red, yellow, brown, or black oxide was to be obtained, depending on how processing is carried out. Early in 1974, troubles in obtaining red oxides from import sources were reported, at least partly due to price difficulties. Spanish iron oxides were in short supply because of worldwide demand.

TECHNOLOGY

Waterborne paint systems were being developed for application in automotive, appliance, coil coating, and general industrial primers and topcoats. This was in response to predictions that waterborne systems will grow to 50% of industrial paint usage within 2 years. Iron oxides will be a major pigment source in these systems, especially synthetic reds and blacks and certain natural reds and browns.[3]

Because several years are required to evaluate pigment resistance to natural weathering, studies were made of accelerated weathering tests. Testing involved variations of the "Dew Cycle" test, applied to red and yellow iron oxides in different binders. Chalking measurements were found to be the best guide to pigment performance.[4]

Preparation and properties of natural and synthetic iron oxide pigments were reviewed in volume 1 of the recently issued Pigment Handbook.[5] The anticorrosion characteristics of paints containing micaceous iron oxide were described.[6] The pigment is prepared from Austrian specular hematite. While little used so far in the United States, paints pigmented with micaceous iron oxide have been been used to protect structural steel for many years in Europe with notable results.[7]

A precipitation process was developed for preparing zinc ferrite yellow pigments having improved high temperature heat stability.[8]

Specifications were developed on the use of excess alkali in the preparation of seed crystals from which acicular gamma ferric oxide for magnetic recording applications was subsequently produced.[9]

Methods continued to be developed for preparing iron oxides from other iron salts contained in waste or byproduct streams of metals or mineral processing operations. The National Research Development Corporation, New Delhi, India, announced plans to produce small tonnages of extra-high-quality red iron oxide pigment, using ferrous sulfate in steel-plant pickling waste as feed material. Sulfate from pickle liquor will be roasted with sodium carbonate, and the reaction mass water-leached to give an iron oxide residue.[10] As from ilmenite chlorination, oxidation of ferric chloride by a mixture of pure oxygen and nitrous oxide was found to yield pigment-grade iron oxide and recyclable chlorine.[11] A process was developed for making a black, iron oxide-containing composite pigment particularly suitable for coloring building materials.[12] It was found that magnetic fluids (ferrofluids) can be prepared from industrial wastes by a precipitation and peptization technique.[13]

Several ways of using iron oxide pigments to produce special-purpose coatings were patented. A method was developed for precipitating extremely small magnetite particles which could be dispersed to form magnetic paint or printing ink.[14] Admixing of amines was found to give flocculation stability to colored iron oxide pigments with good corrosion resistance.[15] An iron oxide-containing solution was devised for simultaneously coloring and preserving wafers of yellow pine dipped into the solution.[16]

In using manganese, chromium, or iron ore to color shaped clay products such as bricks, it was found that better color development was promoted by coaddition of boron-containing fluxes or of other materials.[17]

Different methods of preparing ferrites were tested to determine which gave the most favorable product properties. Freeze drying was found a more desirable solution preparation procedure than either spray drying or coprecipitation in making lithium ferrites.[18] Coprecipitation from a chloride solution as a first step in the preparation of barium ferrite was reported to lead to a higher than customary value for coercive force because of fine particle size and freedom from defects ordinarily caused by milling.[19] A novel technique used to prepare magnesium-manganese ferrite and other ceramic oxide powders consisted of liquid drying aqueous solution droplets in a swirling acetone bath.[20] Magnetic recording disks have been made by spin coating nitrate solution onto metal disks, followed by heating and hydrogen reduction.[21] A titania undercoat improved magnetic properties of ferrite thin films prepared in this manner. Lithium ferrites were reviewed and compared with other spinel ferrites and garnets for microwave applications.[22]

Kyanite and Related Materials

By Michael J. Potter [1]

Kyanite, andalusite, and sillimanite are anhydrous aluminum silicate minerals that are alike in both composition and use patterns and have the same chemical formula, $Al_2O_3 \cdot SiO_2$. Related materials include synthetic mullite, dumortierite, and topaz, also classified as aluminum silicates, although the last two additionally contain substantial proportions of boron and fluorine, respectively. All of these kyanite-group substances have the capability of serving as raw materials for manufacturing special high-performance refractories in the high-alumina category, but there has been no record in recent years of significant utilization of either dumortierite or topaz for this purpose in the United States.

Although published statistics are not sufficiently complete to be wholly conclusive, it appears that the United States, India, and the Republic of South Africa are the leading world producers of kyanite-group minerals and that they may not be far from evenly matched in this regard. It can be presumed that the U.S.S.R. and perhaps a few other industrialized nations also produce significant quantities of these materials.

The trend toward higher performance refractories capable of sustaining an increased number of furnace heats has increased demand for these raw materials. Vigorous worldwide demand for the ingredients used in making a number of special-performance refractories continued in 1974. U.S. exports of kyanite materials in 1974 were 45% above those of 1973. Production and sales of kyanite were discontinued by E. I. du Pont de Nemours & Co., at its Trail Ridge, Fla., operation in mid-1973. There has been speculation about one company's possible interest in the use of kyanite ore as a new raw material source for alumina production.

Legislation and Government Programs.—The allowable depletion rates for kyanite, established by the Tax Reform Act of 1969 and unchanged through 1974, were 22% for domestic production and 14% for foreign operations.

The U.S. Geological Survey's Office of Minerals Exploration provides Government loans of up to 50% of approved costs for the exploration of eligible kyanite deposits; no loans for that purpose were made in 1974.

DOMESTIC PRODUCTION

Kyanite was produced in the United States in 1974 at three open pit mines: Two in Virginia and one in Georgia. Kyanite Mining Corp. operated the Willis Mountain mine in Buckingham County, Va., and the Baker Mountain mine in adjoining Prince Edward County, Va. C-E Minerals, Inc., operated the Graves Mountain mine in Lincoln County, Ga. E. I. du Pont de Nemours & Co., discontinued the production and sale of kyanite in mid-1973 at Trail Ridge, Clay County, Fla. Kyanite had been obtained at this operation as a byproduct from the recovery of titanium and zirconium minerals from a sand deposit.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

Domestic kyanite output in 1974, as measured by the quantity sold or used, was slightly higher in tonnage than in 1973. Specific kyanite production statistics for 1974 (as well as for all previous years since 1949) are withheld to avoid disclosure of individual company confidential data.

Synthetic mullite, produced by five companies in 1974, was 53% less in tonnage than in 1973, and 5% less in total value. The 1974 output was largely high-temperature sintered material, the average unit value of which was twice that of 1973. Electric-furnace fused mullite was produced by A. P. Green Refractories Co. at Philadelphia, Pa., Babcock & Wilcox Co. at Augusta, Ga., and the Carborundum Co. at Niagara Falls, N.Y. High-temperature sintered material was produced by Harbison-Walker Refractories Co. at Eufala, Ala., and NL Industries, Inc. at Greenup, Ky.

Table 1.—Synthetic mullite production in the United States

Year	Quantity (short tons)	Value (thousands)
1970	55,516	$8,840
1971	55,077	4,945
1972	46,389	4,080
1973	58,176	5,211
1974	27,508	4,943

CONSUMPTION AND USES

Kyanite and related materials, conforming to the established end-use pattern, were consumed in 1974 mostly in the manufacture of high-alumina or mullite-class refractories and in lesser quantities as ingredients in some ceramic compositions. Imported Indian kyanite was calcined in its natural lump form, after which it was usually separated into designated particle-size ranges for use chiefly as a grog. Domestic kyanite, already ground to minus 35–mesh as required by the flotation process used in its separation and recovery, was marketed in the raw form or after heat treatment; that is, as mullite, which was sometimes further reduced in particle size before use. In the 35- to 48-mesh range, the mineral was used mostly in monolithic refractory applications such as for high-temperature mortars or cements, ramming mixes, and castable refractories, or with clays and other ingredients in refractory compositions for making kiln furniture, insulating brick, firebrick, and a wide variety of other refractory articles. More finely ground material, minus 200-mesh for example, was used in body mixes for sanitary porcelains, wall tile, precision casting molds, and miscellaneous special-purpose ceramics.

PRICES

Engineering and Mining Journal, December 1974, listed prices for kyanite, f.o.b. Georgia, ranging from $63 to $79 per short ton in bags and $2 less per ton for bulk shipments.

Price ranges quoted for kyanite-group materials in Ceramic Industry Magazine, January 1975, were as follows:

	Per short ton
Andalusite	$30–$60
Kyanite	63–116
Mullite, calcined	82–240
Mullite, fused	160–450

The December 1974 issue of Industrial Minerals (London) quoted kyanite-group price ranges approximately equivalent (with some uncertainty due to a floating exchange rate) to the following:

	Per short ton
Andalusite, Transvaal, c.i.f. main European port	$47–$51
Kyanite, Indian, c.i.f. main European port	86
Sillimanite, Indian, natural bagged, f.o.b.	86
Sillimanite, Indian, calcined, f.o.b. Calcutta	96

FOREIGN TRADE

A substantial increase took place in the amount of kyanite-group material exported, compared with that of 1973. The total amount exported was the highest in history. The tonnage of imported material continued to be small, amounting to slightly less than that of 1973. It can be supposed that the greater part of the material currently being exported consists of mullite. It should be noted, however, that some element of uncertainty is inherent in such conclusions because the Bureau of the Census export figures, on which they are based, do not clearly distinguish synthetic mullite from some other mullite-containing materials prepared by high-temperature processing of certain bauxitic and kaolinitic minerals.

[r] Revised.

WORLD REVIEW

Australia.—The revised figure of 634 tons for sillimanite production in 1972 was about 33% less than that of 1971. This decline in production was said to be largely because of increasing overburden and difficulty in tracing the ore body at both the Acacia and Belmont Quarries in the Broken Hill area of New South Wales (operated by Newbolds General Refractories Ltd.).[2] In 1973 the output of sillimanite was 708 tons.

France.—Andalusite was mined by Denain-Anzin Minéraux at Glomel, and a concentrate with 59.5% Al_2O_3 was produced. Output in 1973 increased to 8,739 tons. Eventual capacity at Glomel is scheduled to be 30,000 to 40,000 tons per year, with reserves said to be several million tons.[3]

Guyana.—Kyanite is one of several as yet little-developed industrial minerals in Guyana. Recently, there has been renewed interest in the kyanite deposits, several of which are currently considered ripe for exploration. For many years bauxite has been the most important of Guyana's mineral export commodities.[4]

---

[2] Black, C. D. G. Sillimanite Minerals. Mining Annual Review (London), June 1974, p. 121.

[3] Work cited in footnote 2.

India.—Production of Indian kyanite increased from 69,977 tons in 1971 to 75,485 tons in 1972, and then decreased to 58,114 tons in 1973. Exports accounted for 43% of production in 1972 and 48% of output in 1973. Belgium, Italy, Japan, and the United Kingdom were the principal recipients of exported material in 1973. Production of sillimanite in 1972 was 4,490 tons with exports amounting to 18% of this amount. Sillimanite production in 1973 was 3,516 tons, and 26% of this amount was exported.

The Geological Survey of India (GSI) reportedly continued its investigations during 1973 to fully assess the country's sillimanite resources, particularly in the Sonapahar region. Regarding sillimanite reserve data, 1967 GSI preliminary estimates were 500,000 tons of "measured ore" (57.0% to 62.2% Al_2O_3) plus 1.5 million tons of inferred reserves (qualities unreported) in the Sonapahar and Jaintia Hills areas.[5]

The Federation of Indian Mineral Industries published a revised and updated survey entitled "Export Possibilities of Minor Minerals."[6] Kyanite and sillimanite were among the several minerals covered in the survey. World reserves, production, and trade were outlined, followed by detailed Indian production and exports. The appendix contained a list of Indian exporters.

South Africa, Republic of.—Five companies extracted andalusite in the Republic of South Africa, one of the world's leading producers. Alluvial deposits in Western Transvaal were worked by four companies, and metamorphosed shales in Eastern Transvaal were processed by one company. The andalusite output in 1973 of 66,912 tons was up 32%, compared with the 1972 figures. Over 25% of total output was exported in 1973.[7] Production of sillimanite was 21,293 tons in 1973, of which nearly 80% was exported.[8]

Sri Lanka.—A survey was completed by the Sri Lanka Geological Survey Department on the Pulmoddai mineral sands.[9] This deposit, located in the northeast of the island, has at least 3.26 million tons of heavy mineral sands in the deposit area above the low water mark. Sillimanite comprises about 1%, with ilmenite and rutile around 80%. The deposit is 4½ miles long and 100 yards wide maximum, and has no overburden. It is said to be one of the richest mineral sand deposits in the world.

United Kingdom.—Imports of kyanite-group minerals amounted to 19,825 tons in 1972. The principal countries of origin and the amounts supplied were Republic of South Africa—51%, India—28%, and France—12%. In 1973 kyanite-group imports were 35,790 tons. The principal countries of origin and the amounts supplied were Republic of South Africa—65%, India—19%, and France—11%.[10]

U.S.S.R.—Extensive deposits of kyanite ores were reportedly discovered in the Keyvy Mountains in Murmansk Oblast. Prospecting has been undertaken at 29 kyanite deposits, of which 6 have been explored. Reserves at these latter deposits are said to amount to more than 3 billion tons. Construction of a mining and concentrating complex is scheduled to begin during the next 5-year period, as are facilities for the production of aluminum alloys and refractory materials.[11]

Kyanite	W	W	W
Synthetic mullite	46,389	58,176	27,508

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Owing to incomplete reporting, the table has not been totaled.

[2] In addition to the countries listed, a number of other countries presumably produce kyanite and related minerals, but output data are not reported and no basis is available for estimates of output levels.

[3] In addition, sillimanite clay (also called kaolinized sillimanite) is produced, but available information is inadequate to make reliable estimates.

TECHNOLOGY

The thermal decomposition of kyanite to mullite and free silica was described.[12] A density reduction of 15% to 17% takes place, and this relatively large density differential was used to measure the degree of decomposition in two typical size fractions of commercial kyanite (minus 35- plus 50-mesh and minus 200- plus 270-mesh). Heat treatment for different lengths of time took place over the 1,200° to 1,400° C range. The main objective of this study was to use pycnometric density measurements as a quick, accurate, and inexpensive method of measuring the degree of conversion of kyanite in commercial calcining processes. In addition, the kinetics of the thermal decomposition of two size fractions of kyanite were discussed.

Kyanite ore, which normally contains between 15% and 20% alumina (Al_2O_3), is being considered as a potential alumina source in Idaho.[13] The company involved is Ethyl Corp., which has expertise in aluminum-based biodegradable detergents.

A patent was issued for the smelting of kyanite or similar material to produce aluminum or aluminum-silicon alloys.[14] Ore is heated to 1,500° to 1,800° C using coal or coke. The prereduced ore is then transferred to an electric arc furnace and heated to 2,000° to 2,300° C where conversion of silicon carbide to elemental silicon and the alumina to elemental aluminum takes place.

Another patent was issued for upgrading titanium-containing kyanite, or other aluminosilicate ores, to obtain a concentrate suitable for making aluminum-silicon alloys.[15] Finely divided ore at elevated temperatures is contacted with hexaclorobutadiene or hexachlorobenzene to drive off chlorides of titanium and iron in vapor form.

Dense mullite brick (70% alumina) is one of the ceramic and refractory materials of potential interest in coal gasification. Conversion of coal to combustible gas starts in the gasifier, which is essentially a refractory-lined steel shell. The gasifier environment places severe demands on refractory linings of the shell as well as the combustors, regenerators, cyclones, and connecting ducts. The linings must withstand the corrosiveness, erosiveness, and general reactivity of the hot, high-velocity, high-pressure, particulate-laden gas stream. Since there are no closely analagous applications, it is not known how refractories will perform in this environment.[16]

The use of plastic monolithic refractories, including mullite-based types, in kiln linings was discussed.[17] Construction is usually accomplished by pneumatically operated bench rammers. Plastic refractories are composed of crushed or ground calcined aggregate bonded with specific clays and chemicals, mixed and packaged to a specific workability to permit handling and ramming in place. The plastic construction is said to have several desirable aspects, including fuel savings.

[16] Hall, A. M. Coal Gasification Poses Demanding Material Requirements. Mater. Eng., v. 80, No. 1, July 1974, pp. 16–18.

Chemical analysis of refractories, including mullite, by X-ray fluorescence was described.[18] Three sample preparation methods were evaluated: Pressed powders, borate fusions, and sodium-silicate melts. Mineralogical problems were encountered with pressed powders, and incomplete refractory solution was found with borate fusions. Sodium-silicate glass melts produced durable samples and reportedly the best results.

A patent was issued for the formation of mullite in clay wares.[19] Lower firing temperatures are achieved by incorporating in the clay mix about 1% to 3% of a fluorine compound, such as fluorspar or topaz. A patent for a new type of mullite brick refractory containing from 56% to 80% mullite, 6% to 13% calcined kyanite, 5% to 8% alumina, 1% to 9% silica, and 4% to 25% iron-chromite ore was granted.[20] This new refractory is said to have increased service life and decreased alkali and slag attack when used in the steel industry. A summary of the main types of refractory products, including mullite, was given.[21]

Refractory mullite was one of the materials for which mechanical and electrical properties were listed in a summary table.[22]

Phases in the kaolinite-mullite reaction sequence were reexamined by infrared absorption spectrophotometry.[23]

Lead

By J. Patrick Ryan [1] and John M. Hague [1]

World mine production, which had been trending upward for several years, dropped slightly in 1974 but smelter production increased marginally from the record high level of output achieved in 1973. World metal consumption decreased about 1% but exceeded production by nearly 4%, the shortfall in production being balanced essentially by withdrawals from producers and Government stocks. The U.S. lead price advanced to a record high in 1974 following removal of price controls in December 1973. The U.S. producers average price reached 24.5 cents per pound late in June, virtually the same as the London Metal Exchange (LME) price. The average equivalent LME price exceeded the U.S. producers price during the first 8 months of the year then fell slightly below the U.S. price in the last 4 months. The average equivalent LME price in 1974 was 26.83 cents per pound. The average domestic price of lead on a nationwide basis in 1974 was 22.53 cents per pound.

Domestic mine production increased 10% in 1974 to a 47-year record high, but smelter production was slightly lower than the 43-year high level achieved in 1972. Secondary smelter output increased 7% to nearly 698,700 tons, a new record representing about 50% of total smelter and refinery production of lead.

Consumption of lead reached a record high of 1.6 million tons, nearly 4% more than in 1973. Lead requirements in the transportation field continued to grow, accounting for 69% of total lead consumption in 1974. Storage battery requirements increased 11%, more than offsetting a 9% decline in lead used in gasoline antiknock compounds. Moderate gains were recorded in the quantity of lead used in pigments and ammunition which together accounted for 13% of total consumption.

Stocks of refined lead and lead in antimonial lead at primary plants increased 43% during the year to 37,300 tons at yearend. Consumers stocks of refined soft lead and lead in antimonial lead and other alloys increased 34% to 165,400 tons at yearend.

Park City Ventures, jointly owned by The Anaconda Company and American Smelting and Refining Co. (ASARCO Inc.) continued development work and construction of a 750-ton-per-day concentrator at the Ontario zinc-lead mine, Park City, Utah. The mine is scheduled for production in April 1975.

Legislation and Government Programs.—The General Services Administration (GSA) reported that commitments to purchase surplus lead from the Government stockpile totaled 229,320 tons in 1974. Of the total about 151,230 tons represented commercial commitments through producers; the remaining 78,090 tons represented transfers for Government use and commitments under the set-aside program. The uncommitted surplus at yearend was 534,643 tons, of which 69,751 tons excess to stockpile requirements was available for disposal. Actual physical drawdown of Government stocks during 1974 was 265,676 tons, leaving a total inventory in storage of 608,654 tons on December 31. The shelf-item disposal program of direct sales to consumers and transfers for direct Government use ended on December 31, 1974. The unsold balance reverted to the long-term disposal contracts with primary domestic producers.

A bill (H.R. 14845) was introduced in the Congress to authorize the disposal of 464,900 tons of lead from the national and supplemental stockpiles. By yearend, no further action had been taken on the bill.

---

[1] Physical scientist, Division of Nonferrous Metals.

Proposed regulations to phase out lead shot for water fowl hunting throughout much of the United States starting in 1976 were published in the Federal Register. Public hearings were held in four cities but a final decision had not been reached at yearend.

In October the Environmental Protection Agency (EPA) published standards of performance for new and modified sources for primary copper, lead, and zinc smelters under authority of section 111 of the Clean Air Act, as amended. The proposed standard for sulfur dioxide (SO_2) emissions was designed to reflect the degree of limitation attainable through the application of the best available technology. The basic standard for primary lead smelters would prohibit the discharge of any gases which contain more than 0.065% sulfur dioxide by volume.

On December 20 the U.S. Circuit Court of Appeals for Washington set aside the EPA regulations for a gradual phasedown of lead in gasoline by a two-to-one vote. The phasedown which was scheduled to begin on January 1, 1975, would direct that gasoline refiners reduce the average lead content of gasoline over a 4-year period from 1.7 grams per gallon after January 1, 1975, to 0.5 gram per gallon after January 1, 1979. The formal written opinion on an appeal by Ethyl Corp. and others, challenging the health aspects set forth by EPA, was issued in January 1975. The Court found that evidence did not support the EPA contention that auto emissions contributed significantly to blood lead levels in adults and children and that issuance of the EPA regulations was arbitrary and capricious.

Table 1.—Salient lead statistics

(Short tons unless otherwise specified)

[r] Revised.

[1] Quotations for 1970–71 at New York and for 1972–74 on a nationwide, delivered basis.

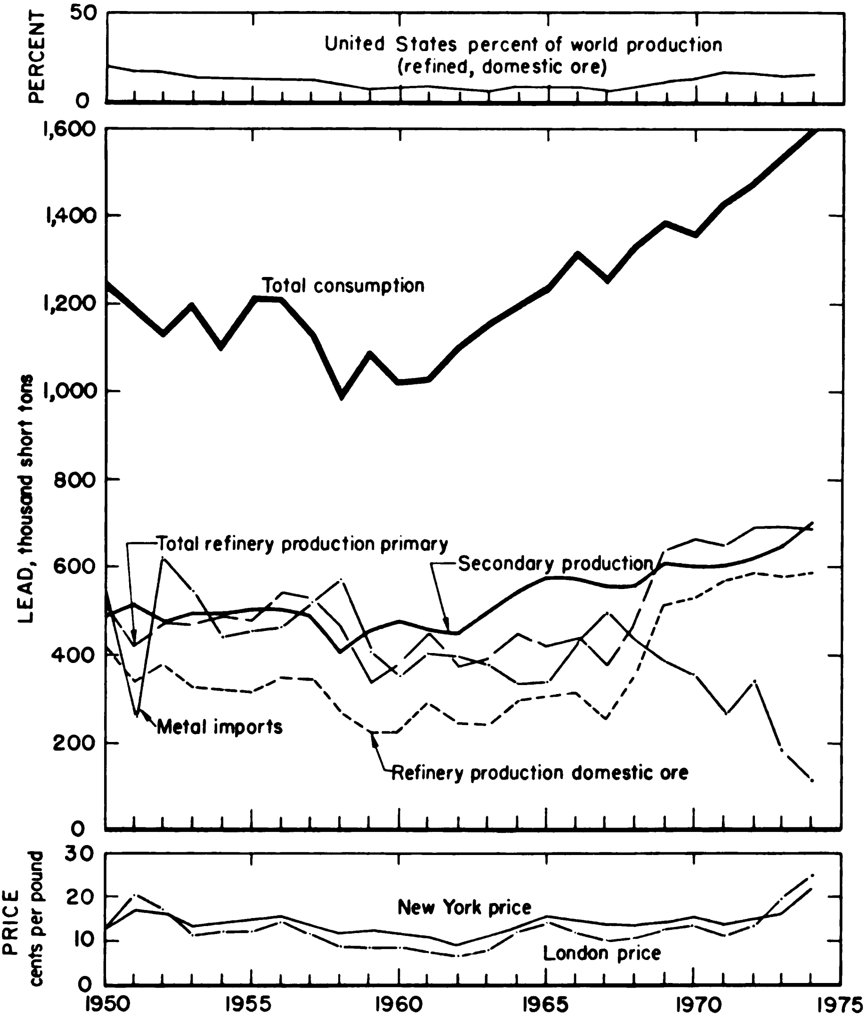

Figure 1.—Trends in the lead industry in the United States.

DOMESTIC PRODUCTION

MINE PRODUCTION

Continuing an almost uninterrupted rising trend since 1962, mine production of lead increased 10% in 1974 to nearly 663,900 tons, the highest level of output since 1927. Monthly production reached a maximum of 64,900 tons in October, nearly 9,000 tons more than the maximum achieved in 1973. Production from Missouri mines increased 15% to a record high of 562,100 tons and accounted for nearly 85% of the Nation's total. Output in Idaho, which provided 8% of the total, was down 10,000 tons from the 1973 level. Colorado's production declined 3,500 tons in 1974. Utah's output of lead continued to decline reaching the lowest level in more than 70 years. Lower production at Kennecott's Burgin mine in Utah County, the State's only lead-producing mine, was attributed to adverse operating conditions including groundwater problems and high temperatures. Kennecott's Ozark mine in Missouri achieved record production in 1974 with an output of 74,500 tons of lead in concentrates compared to 59,000 tons in 1973.[2]

The Buick mine jointly owned by Amax Lead Co. of Missouri (AMAX) and Homestake Mining Co. was the leading producer for the fourth consecutive year with an output of 1.56 million tons of ore, about the same as in 1973. However, lead concentrate production increased about 11% in 1974 to 250,600 tons.[3]

The seven leading mines, all in Missouri, contributed 80% of the total U.S. mine production of lead. The 12 leading mines produced 90%, and the 25 leading mines accounted for 99% of the total. About 5,100 persons were employed in the Nation's lead, lead-silver, and lead-zinc mines and mills in 1974. Output of lead and zinc from these mines per man-year was approximately 127 tons. Average grade of lead ore mined was 6.24% lead and 1.01% zinc compared with 6.55% lead and 1.08% zinc in 1973.

St. Joe Minerals Corp., the Nation's largest lead mining company, continued to operate its four mine-mill units in southeast Missouri and reported that 1974 production of lead in concentrate increased 43,436 tons to 247,494 tons.[4] The production gain was largely due to near-capacity operations at the corporation's new Brushy Creek mine which began operation in 1973.

Hecla Mining Co. reported that production at its Lucky Friday mine in the Coeur d'Alene district, Idaho, was 165,700 tons of ore assaying 9.93% lead, 1.18% zinc, and 13.53 ounces of silver per ton compared with 176,900 tons assaying 11.14% lead, 1.22% zinc, and 15.49 ounces of silver per ton in 1973. The decrease in mine output was attributed to a shortage of experienced underground miners. Ore reserves at Lucky Friday at yearend totaled 539,000 tons compared with 510,000 tons a year earlier. Hecla also reported that ore production at the Star-Morning mine jointly owned by Hecla (30%) and The Bunker Hill Co. (70%) increased 15,800 tons to 281,580 tons. Hecla's share of the 1974 production of lead-zinc-silver ore was 84,470 tons assaying 4.77% lead, 6.04% zinc, and 2.45 ounces of silver per ton. Hecla's share of the computed ore reserves increased 90,000 tons to 376,000 tons at yearend.[5]

In Colorado, Idarado Mining Co. treated 396,600 tons of lead-zinc-copper ore averaging 2.46% lead, 3.33% zinc and 0.55% copper compared with 378,200 tons milled in 1973 averaging 2.55% lead, 3.44% zinc, and 0.56% copper. Ore reserves at yearend 1974 increased 20% to 3.88 million tons averaging 3.13% lead, 4.41% zinc, 0.69% copper, 1.77 ounces of silver and 0.02 ounce of gold per ton. The Leadville mine (Resurrection mine) a joint venture of ASARCO and Newmont Mining Corp., milled 163,000 tons of lead-zinc-silver ore in 1974, about 43,000 tons more than in 1973. However, manpower shortages continued to retard operation of the mine at full capacity. Ore reserves at yearend were estimated at 2.65 million tons averaging 5.0% lead, 9.4% zinc, 2.4 ounces of silver and 0.07 ounce of gold per ton.[6]

Bunker Hill reported that production from company owned and controlled mines in 1974 aggregated 31,000 tons of lead, about the same as in 1973. The company also reported that proven and probable ore reserves at yearend in the Bunker Hill mine totaled 3.27 million tons averaging 2.2% lead, 3.5% zinc and 1.2 ounces of silver per ton. The company also reported that at yearend its 70% interest in proven and probable reserves in the Star mine totaled 849,500 tons averaging 6.7% lead, 7.2% zinc, and 3.8 ounces of silver per ton.[7]

SMELTER AND REFINERY PRODUCTION

Output of refined lead from the Nation's five primary refineries in 1974 dropped slightly below production in 1973 as the gain in metal recovered from domestic concentrates failed to offset a decline in metal recovered from foreign ores and concentrates. However, total primary metal production of 682,900 tons was the largest annual output since 1929. About 86% of the total output was recovered from domestic ores compared with 84% in 1973. Antimonial lead production at primary refineries declined 19% to 12,513 tons, continuing a general downward trend since 1968. The average antimony content of the alloy increased 1.3% to 8.8%, the highest level since 1967.

[7] Gulf Resources & Chemical Corp. 1974 Annual Report. P. 11.

Metal production at the Herculaneum, Mo., smelter of St. Joe Minerals Corp. reached capacity in 1974 with a production of 230,870 tons of lead metal and lead alloys, about 15,900 tons more than in 1973.[8]

ASARCO reported that lead production at its Omaha and Glover refineries, totaling 218,600 tons, was about 9% less than in 1973. The Omaha, Nebr., refinery treated base bullion essentially from the company's custom smelters at El Paso, Tex., and East Helena, Mont. Most of the concentrate treated at the Glover, Mo., smelter-refinery came from Kennecott's Ozark mine at Sweetwater, Mo. The East Helena smelter, operating at 78% of rated capacity during the year, processed ore and concentrate from about 110 domestic mines in 7 States and from mines in Canada, Peru, and Australia. The El Paso lead smelter, operating at 67% of capacity in 1974, processed ore and concentrate from approximately 36 domestic mines in 8 States and from mines in Peru, Canada, Honduras, Nicaragua, Australia, and Mexico. The smelter was closed by a strike for 5 weeks during the year. The company reported the installation of a computerized monitoring system at the Glover smelter to give early warning of increases in the sulfur dioxide content of ground-level air so that operations can be curtailed when necessary to assure compliance with State and Federal ambient air standards.[9]

The AMAX-Homestake smelter-refinery at Boss, Mo., produced 134,300 tons of refined lead, approximately one-half of which was derived from concentrates treated on toll for others.[10]

At the Bunker Hill smelter-refinery of Gulf Resources & Chemical Corp., lead production declined about 6% to 123,000 tons. The lower output was attributed largely to interruption of operations, caused by storms and a 10-day labor strike by craft unions. In addition production was curtailed occasionally during weather inversions to meet sulfur dioxide emission standards.[11] The Bunker Hill smelter processed concentrates from mines in six States and from mines in Canada and Peru.

Secondary smelter production of lead from recycled materials increased nearly 7% to a new record output of 698,700 tons, about 50% of the total smelter and refinery production. Approximately 130 secondary plants were engaged in recovery of lead and lead alloys from scrap materials during the year. Secondary metal output represented about 44% of total lead consumption in 1974. About six plants engaged in processing lead scrap closed during the year.

U.S.S. Lead Refinery, Inc., a subsidiary of U.V. Industries, Inc., expanded its facilities for processing scrap lead materials at East Chicago, Ind., which will more than double the company's production of antimonial and soft lead.

RAW MATERIAL SOURCES

Primary smelters and refineries processed ores and concentrates from domestic mines yielding 586,000 tons of refined lead and antimonial lead. This represented nearly 86% of total primary production, compared with 84% in 1973. Refined and antimonial lead recovered from imported concentrates smelted during the year amounted to 96,900 tons, about 14,600 tons less than in 1973. Lead recovered from lead scrap processed at primary plants increased to about 1,500 tons contained in antimonial lead compared with 1,100 tons in 1973.

Scrap materials consumed in 1974 totaled 929,100 tons, 61,400 tons more than in 1973. About 95 secondary smelters accounted for nearly all of the total scrap consumed. New scrap in the form of purchased drosses and residues from a wide variety of sources aggregated 129,400 tons, about 14% of the total scrap processed compared with 154,700 tons, about 18% of the total input in 1973. The remainder, old scrap, was largely battery plates, with small quantities of cable lead, type metal, solder, babbitt, and soft and hard lead.

A small amount of reclaimed scrap, totaling only 1,200 tons in 1974, was imported for processing in domestic plants.

CONSUMPTION AND USES

Domestic consumption of lead increased nearly 4% in 1974 to a new record of 1.60 million tons. On a monthly basis consumption ranged from a low of 112,800 tons in July to a new record high of nearly 157,000 tons in October. Use of lead increased in all major product sectors except chemicals (gasoline antiknock additives) which declined nearly 9% from the 1973 level and accounted for about 16% of total lead consumption. The 6% increase in the metal products sector, which accounted for 74% of the total consumption, represented gains in battery requirements and, to a lesser extent, ammunition. These gains more than offset combined losses in metal used in bearings, pipes, sheets, and solder. Changes in metal consumed in most other metal products were relatively minor. According to type of material consumed, soft refined lead represented 66% of the total consumption, antimonial lead accounted for 29%, and lead in other alloys, mainly solders and bearing metals, accounted for 4%. Lead in copper-base scrap accounted for 1% of total consumption.

Lead requirements for battery grids and oxides increased 11% and accounted for 53% of total lead consumption. The gain in battery lead consumption reflected increased demand for batteries used for power in starting, lighting, and ignition (SLI), and traction of motor vehicles, both on-the-road and off-the-road types. A total of 55.7 million SLI-type batteries was produced in 1974, 1.4 million less than in 1973. Of the total battery production, about 44.4 million were replacement, 10.1 million were original equipment, and the remainder were exported. The 9% drop in the quantity of lead used in antiknock compounds in 1974 reflected a reduction in the average lead content per gallon of gasoline from about 2.2 grams per gallon in 1973 to about 1.90 grams per gallon, and a 2.5% drop in total gasoline production.

Lead used in pigments, particularly red lead and litharge, increased 7% and accounted for 7% of the total consumption in 1974. Miscellaneous and other unclassified uses increased 6% and accounted for 3% of the total. About 5% of the total was used for ammunition. Lead used in metal products, other than battery components and ammunition, accounted for approximately 15% of total consumption.

The domestic supply of lead metal from all sources—primary and secondary production, imports for consumption, industry stock changes, and stockpile releases—totaled about 50,600 tons more than reported consumption and exports. The apparent excess supply in 1974, amounting to about 3% of reported consumption, was attributed partly to unreported consumption, incomplete export data, and stock buildup, especially by small producers and dealers that do not report to the Bureau of Mines.

LEAD PIGMENTS

Pig lead used in the production of lead oxides and pigments totaled nearly 558,000 tons, about 9% more than in 1973. The quantity of lead used in making black oxide increased 20% and accounted for 70% of the total lead in pigments. Litharge production was down 12% and accounted for 26% of the total in 1974. Most of the litharge shipments went to battery manufacturers and is included in "Other" in table 20. Litharge shipped for use in the ceramics industry increased nearly 30% constituting 29% of the total litharge shipments in 1974.

Prices.—The published price of basic carbonate white lead in carload lots, freight allowed, remained unchanged at 23.9 cents per pound, the same as in 1973. The quoted price of red lead (Pb_3O_4) 95%, in carload lots at works, was unchanged at 21–21.2 cents per pound through April, then was advanced to 26 cents in May, to 27.75 cents in June, 27.75–29.25 cents in July, and remained unchanged thereafter to yearend. The price quotation of lead silicate ($PbSiO_3$) remained unchanged at 23 cents during the year. The price quotation for commercial-grade litharge in carload lots at works remained unchanged at 21.25–22.75 cents until May when the price was increased to 22.75–25.25 cents. The price was again increased in June to 26.50–27.25 cents and to 27.25–28.75 cents in July, remaining unchanged thereafter to yearend.

The value of shipments of white lead, red lead, and litharge amounted to $89.2 million, an average of $494 per ton compared with $72.9 million and $356 per ton in 1973.

Foreign Trade.—Imports for consumption of lead pigments and compounds decreased 30% in quantity but the value increased 16% to $10 million. Litharge, which comprised 60% of the total quantity imported, decreased 40%; imports of chrome yellow, comprising 30% of the total, were 3% less than in 1973. Virtually all of the imports of litharge came from Mexico; about two-thirds of the chrome yellow came from Japan.

Exports of pigment-grade lead oxides totaled 3,390 tons valued at $1.92 million and exports of lead oxides other than pigment grade amounted to 1,680 tons valued at $1.51 million. Shipments went to 25 countries.

STOCKS

Inventories of refined and antimonial lead at primary smelters and refineries trended downward in the first 7 months of 1974 from about 26,100 tons at the beginning of the year to a low of 17,600 tons at the end of July then trended upward through the next 4 months to 24,600 tons at the end of November. In December refiner's stocks increased sharply to about 37,300 tons at yearend, indicating a gain of 11,200 tons for the year. Stocks of lead in base bullion at yearend were about 3,300 tons less than a year earlier, but the lead content of ore and matte stocks increased nearly 23,400 tons.

Stocks of lead in all forms at consumer and secondary smelting plants totaled nearly 166,600 tons at yearend, about 42,500 tons more than at yearend 1973. Refined soft lead constituted 64% of the total compared with 68% in 1973.

Stocks of refined lead, lead in antimonial lead, and lead in alloys at producers and consumers plants totaled 202,600 tons representing less than 2 months' domestic consumption. Stocks of new and old lead scrap at secondary smelters increased about 19,900 tons to 104,100 tons at yearend.

PRICES

The U.S. producer price for common and corroding-grade lead on a nationwide basis as reported by Metals Week advanced on January 4 from a split quotation of 18–19 cents to 19.0 cents per pound. In the last week of March the price was advanced again to 21.5 cents remaining unchanged until mid-June when the price quotation was split at 21.5–24.5 until June 21 when all producers quoted 24.5 cents per pound, a new record high; thereafter, the lead price remained unchanged to yearend. The weighted average monthly U.S. producer price ranging upward from 18.98 cents in January to 24.50 cents in December, indicated a 29% gain during the year. The average price for the year was 22.53 cents compared with 16.29 cents in 1973.

The London Metal Exchange (LME) cash bid price for lead in terms of U.S. currency, trended upward in the first quarter from an average of 25.62 cents per pound in January to 32.13 cents in March, declining steadily thereafter to a low of 24.17 cents in November, and rising slightly to 24.20 cents in December. The LME price exceeded the U.S. price during the first 8 months of 1974 and was near parity with the U.S. price during the last 4 months of the year. The average LME cash price for the year was 26.83 cents, based on a monthly average Sterling Exchange rate of 233.93 cents, compared with an average price of 19.47 cents, in 1973 with Sterling Exchange averaging 245.10 cents.

FOREIGN TRADE

Exports of lead metal, lead alloys, and scrap materials declined 4% in 1974 below the record high level established in 1973. Metal and alloy exports totaled nearly 62,000 tons, about 4,600 tons less than in 1973, whereas scrap outflow (59,400 tons) was only slightly less than in 1973. About 61% of the total wrought and unwrought metal exported went to west European countries; most of the remainder went to Brazil, Canada, and Japan. Nearly 38% of the scrap shipments went to

Canada and the remainder to about 22 other countries. In addition 111,200 tons of lead and zinc concentrates was exported. Nearly one-half of the concentrates was shipped to Japan; and most of the remainder went to Belgium-Luxembourg (26%), Brazil (10%), Romania (15%), Yugoslavia (4%), and Mexico (4%). The quantities of lead and zinc contained in the concentrates are not available separately.

General imports of lead materials into the United States in 1974 dropped 26% to a total of 214,700 tons valued at $92.1 million. Receipts of lead in concentrates and other unrefined materials were down 13%, and metal receipts dropped 34% from the 1973 level of imports to about 118,400 tons, the smallest quantity of metal imported since 1946. As in 1973 the decline in lead imports in 1974 was attributed partly to the effect of the lead dumping determination by the International Trade Commission against Canadian and Australian exporters. Metal receipts from Australia and Canada were approximately 42,000 and 22,000 tons, respectively, less than in 1973.

Peru was again the leading supplier of crude lead materials with nearly 28% of the total imports; shipments from Australia, Canada, Honduras, and Mexico accounted for most of the remainder. Canada, Peru, and Mexico together furnished 92% of the total metal imported.

WORLD REVIEW

Mine production of lead in 1974 in market economy countries of the world, based on data compiled by the Bureau of Mines, totaled 2.71 million tons, about 8% less than in 1973. Mine production in centrally controlled economy countries, including Yugoslavia, was estimated to be 1.13 million tons, 29.5% of the total world production of 3.84 million tons. Smelter production of lead in market economy countries, limited to primary metal where possible, totaled 2.64 million tons and the output from centrally controlled economy countries was estimated to be 1.18 million tons yielding a world total of 3.82 million tons. Compared with 1973, the 1974 world mine production showed an 0.8% decline, whereas the world smelter production registered a 0.6% gain.

The United States increased its lead as the country producing the most lead from mine sources, accounting for 17% of the world total. Other countries producing over 100,000 tons of lead in mined ore were the U.S.S.R., Australia, Canada, Mexico, Peru, Yugoslavia, Bulgaria, North Korea, and the People's Republic of China, in descending order of quantity mined. The North American continent produced 1.29 million tons or 34% of the world total.

The United States again was the leading producer of primary lead metal. The U.S.S.R. probably ranked second, followed by Australia, Mexico, Japan, France, Yugoslavia, Canada, West Germany, Bulgaria, the People's Republic of China, North Korea, and Belgium. Each of the 13 countries produced over 100,000 tons of lead and collectively they accounted for 79% of the 1974 world production. The smelter output data for Yugoslavia, Bulgaria, and Belgium may include recovery from secondary materials.

Data released by the International Lead and Zinc Study Group (ILZSG) on consumption of refined lead in market economy countries estimated a total of 4.07 million tons in 1974, about 0.2% more than the final figure for 1973. The greatest increase was in the United States which accounted for 37% of world market economy consumption; France, West Germany, Japan, and the United Kingdom registered decreases in consumption in 1974. ILZSG reports of world lead metal production showed a deficit in supply of 130,000 tons in 1974 probably accounted for by combined changes in producers stocks and the U.S. Government stockpile.

Australia.—Due to reduced output from Broken Hill mines, mine production of lead in 1974 was 7% below that of the previous year and totaled 415,900 tons. The Zinc Corporation (ZC) and New Broken Hill Consolidated (NBHC) mines were handicapped by delays in development brought on by caving in stopes of the NBHC mine in 1973, by labor disputes, and a shortage of manpower. Nonetheless Australia remained the world's third ranking lead-producing country.

The combined production of refined lead

and lead bullion within Australia was 374,800 tons, about the same output as in 1973. Broken Hill Associated Smelters, Pty. Ltd., a subsidiary of Conzinc Riotinto of Australia, Ltd., at Port Pirie produced 222,600 tons of refined lead. Mount Isa Mines Ltd., 49% owned by ASARCO, at Mount Isa produced 139,200 tons of lead in unrefined products during fiscal 1973–74; and Sulphide Corp., Pty. Ltd., a subsidiary of Conzinc Riotinto produced 27,500 tons of lead bullion for refining elsewhere.

Consumption of primary lead in Australia declined about 4% in 1974 from the record level of 1973. Batteries, using metal and oxides, accounted for 48% of the total 54,100 tons of primary lead consumption. Total lead consumption was estimated to be 92,600 tons including refined pig lead and lead content of antimonial lead.

Canada.—Mine production of lead contained in ores and concentrates was below normal capacity in 1974 and decreased 15% from the 1973 output to about 365,000 tons. Production of primary refined metal dropped from 206,000 tons in 1973 to 138,000 tons in 1974. Strikes or lockouts at mines operated by Cyprus-Anvil Mining Corp., Brunswick Mining & Smelting Co. Ltd., and Cominco, Ltd., reduced mine production, and a 4-month strike at Cominco's Trail, British Columbia, plant cut refined metal production.

As a result of a U.S. International Trade Commission finding of injury from lead imports, shipments of lead to the United States from Canada were reduced to avoid penalties for dumping. Exports of refined lead worldwide decreased 37% to 79,050 tons, with 40% going to the United Kingdom and 39% to the United States. Exports of concentrates were maintained at a high level, totaling 213,900 tons of contained lead; 58% went to Japan, 13% to the United States, 10% to West Germany, and the balance to other European countries and Brazil. Consumption of primary metal within Canada was estimated at 75,000 tons in 1974. Secondary recovery was about 38,000 tons in 1974. Imports of refined lead in 1974 were 12,500 tons mostly from Japan and the United States.

The Yukon Territory provided the largest share of lead mine production with 32% of the total; Northwest Territories ranked second with 27%; British Columbia, 18%; New Brunswick, 15%; Newfoundland, 4%; Ontario, 3%; and three other provinces 1% of the total.

One of the two largest mine sources of lead was the Faro operation of Cyprus-Anvil Mining Corp. in Yukon Territory. This open pit mine and concentrator produced over 96,000 tons of lead in concentrates in 1974 from an ore body estimated to contain 63 million tons averaging 3.40% lead, 5.72% zinc and 1.19 ounces of silver per ton.

The second largest lead mine was operated by Pine Point Mines Ltd., a subsidiary of Cominco, Ltd., located at Pine Point in Northwest Territories. The estimated lead production in 1974 was about 90,000 tons. Ore reserves reported at the end of 1974 were 40 million tons averaging 7.8% combined zinc and lead; in past years the lead content has been about one-third of the combined assay. Cominco also produced concentrates containing about 60,000 tons of lead from the Sullivan mine in British Columbia.

Brunswick Mining & Smelting Corp. Ltd., owned 64% by Noranda Mines Ltd., produced 44,200 tons of lead from its mines near Bathurst and its smelter at Belledune, New Brunswick.

Greenland.—The Black Angel mine at latitude 71° N. successfully completed its first full year of production yielding 634,000 tons of ore containing 111,000 tons of zinc and 32,000 tons of lead. Greenex A/S, 62% owned by Cominco, Ltd., is the operating company in this territory of Denmark. Ore reserves were reported as 3.86 million tons with 15.7% zinc content and 5.1% lead content. Lead and zinc concentrates were sold to western European smelters mainly on the British market.

Honduras.—Rosario Resources Corp. reported that the El Mochito mine had the best year in its history. The company reported that production in 1974 from 328,000 tons of ore yielded 22,700 tons of lead, 25,600 tons of zinc and over 3 million ounces of silver. Total ore reserves in the area were increased to 5.8 million tons with an average grade of 5.10% lead, 8.60% zinc, 0.26% copper and 5.73 ounces of silver per ton. Rosario participated in a joint exploration venture with ASARCO Inc. to explore the old Rosario mine in depth.

Ireland.—Construction and development work at the Navan mine were suspended by Tara Exploration and Development Co. Ltd., in August 1974 because terms of the proposed State Mining Lease offered by the Irish Government were unacceptable. During the suspension, negotiations continued and agreement on a revised lease was announced in February 1975. As a result of the delay and of world-wide inflation, the estimated capital cost of the project was increased from $87 million (in 1973) to $150 million (in early 1975). Prior to the shutdown, 95,000 tons of development ore estimated to grade 11.4% zinc and 2.4% lead was stockpiled on the surface. The mine and concentrator were being designed to treat about 2.5 million tons of ore annually.

Mogul of Ireland, Ltd., a subsidiary of International Mogul Mines Ltd., operated its mine near Silvermines in County Tipperary and reported production of 23,600 tons of lead concentrate and 96,300 tons of zinc concentrate. Ore reserves were estimated at 8,470,000 tons averaging 2.75% lead and 6.48% zinc.

Irish Base Metals Ltd., a subsidiary of Northgate Exploration Ltd., operated the Tynagh mine in County Galway and produced concentrates containing 26,500 tons of lead, 19,700 tons of zinc and 870,000 ounces of silver in 1974.

Mexico.—Lead mine production increased 22% from 1973 to 1974 to a total of 240,300 tons. Industrial Minera Mexico, S.A. had a lead output of 108,200 tons and Industrias Peñoles S.A. reported production of 107,000 tons. Only 15,000 tons of lead in concentrates were produced for export by Mexican mines. Industrial Minera was modernizing its lead smelter in Chihuahua to achieve a capacity of 130,000 tons per year by 1976. Met-Mex Peñoles, S.A., a subsidiary of Industrias Peñoles, continued making improvements to the sintering, sulfuric acid, and refining plants at Torreón, designed to increase capacity to 190,000 tons per year and reduce atmospheric pollution.

In April 1974, ASARCO sold part of its equity in Industrial Minera Mexico (formerly Asarco Mexicana S.A.) to Mexican investors reducing its residual ownership to 34% of the outstanding stock.

Morocco.—Lead was the second most important mineral export of Morocco (after phosphate rock), even though production dropped 20% by metal weight, or 11% by concentrate weight, to 141,000 tons of concentrates in 1974. The largest lead mine located at Zeida maintained the same level of production as in 1973, producing 40,000 tons of concentrate. Three other mines, at Touissit, Aouli, and Aoum, had decreased activity due either to a strike or depletion of reserves in the older parts of the mine.

Discussions with the U.S.S.R. for geological studies in the northern Rif Mountains concentrated on exploration for lead and zinc in this region. A new lead smelter was planned for the Meknes area to accommodate the production of several small mines.

Peru.—With a mine production of 224,900 tons of recoverable lead, Peru ranked sixth among lead-producing nations in 1974. This output was used to produce 88,850 tons of refined lead with most of the balance exported as concentrates. The lead exported from Peru included 26,200 tons in lead concentrates and 40,000 tons of lead metal shipped to the United States.

At the El Povenir mine, Cía, Minera Milpo was expanding capacity from 1,000 to 1,800 tons of ore per day, and was planning to increase lead concentrate production to 22,000 tons per year. El Porvenir ore averaged 4.3% lead, 6% zinc, and 5 ounces of silver per ton.

The Santander mine of the St. Joe Minerals Corp. continued development to convert from the former open pit operation to a completely underground operation using trackless mining equipment on three new levels. Production of lead concentrate was at the rate of 10,000 tons per year.

Spain.—Spanish lead production was expected to increase by 40,000 tons per year within the next few years. The Rubiales zinc-lead mine in the province of Lugo in northwestern Spain was scheduled for development in 1975 and initial production by 1977. The principal shareholders were Cominco Europe N.V., 47.5%; Union Corp. (Luxembourg) S.A., 27%; and Dugwill Pty., Ltd., Asturiana de Zinc S.A., and Banco Urquijo S.A. sharing the balance. At full production the Rubiales mine will have an annual production of 16,500 tons of lead concentrate and 126,000 tons of zinc concentrate. Another zinc-lead development project, the d'Aznacollar mining complex of d'Aznacollar d'Andaluza de Piritas S.A. (APIRSA) was started during 1974 with full production of 42,000 tons of lead concentrate and 98,000 tons of zinc concentrate expected by 1978. A zinc-lead mine being developed by Asturiana at Huelva was due to reach capacity in 1975 producing 3,300 tons of lead and 7,700 tons of zinc. A new lead smelter was planned at Linares to be built by a consortium of Cía. La Cruz, Cie. Royale Asturienne des Mines S.A., EN Adaro, Société Minière et Metallurgique de Peñarroya and Cia. Minero Metallúrgica Los Guindos S.A.

Yugoslavia.—Trepča Enterprises continued to work toward increased lead and zinc mine capacity by renovating or developing five mines in Serbia and one mine in Montenegro. The concentrates are to go to the Trepča at Zvečan. Two new lead and zinc mines were planned in Macedonia with a total capacity of 1.5 million tons of ore per year. Concentrates from the Macedonia mines will be processed in the smelter at Titov Veles.

TECHNOLOGY

The International Lead Zinc Research Organization (ILZRO) reported that batteries and environmental health were the principal areas of its research activities in 1974. Fundamental research in the battery area to improve technology was directed toward obtaining a better understanding of the mechanisms of active material shedding in the positive electrodes of the lead-acid system, effects of minor constituents in the system, the effect of aging of grids on anodic corrosion, and new approaches to paste mixing. The basic thrust of fundamental research conducted in cooperation with the U.S. Naval Research Laboratory (NRL) was to improve efficiency and power density of the lead-acid battery as well as to determine the active material softening failure mechanism of the PbO_2 electrode.

ILZRO research in the environmental health area included investigations of population and occupational exposures to lead. Studies completed on a large group of workers employed in lead production facilities or battery plants over a 23-year period disclosed that the life expectancy of lead workers is approximately the same as that of all U.S. males. A study conducted in Tokyo, Japan of policemen exposed to low concentrations of lead in areas of heavy traffic concluded that at the present level of lead in air in Tokyo, no direct relationship between lead levels in blood and urine could be established.

Other ILZRO lead research was directed toward developing new low-cost alloys for the electric power industry, improved methods of splicing cable sheathing, fundamental work in the ceramics area, and field evaluation of synthesized organolead compounds.

Gould Inc. announced that it had developed a new heavy-duty battery, impervious to vibration, that operated corrosion free and required no water. The lead-calcium, maintenance-free battery retains its charge 6 to 8 times longer than ordinary batteries and has up to 30% more cranking power.

The transition to lead-calcium instead of lead-antimony grids will have an economic effect on secondary lead smelters as the antimony profit will be largely lost when large volumes of battery scrap are recycled.

Bureau of Mines engineers at Spokane, Wash., completed a comprehensive study of the Nation's primary lead resources to determine the degree of U.S. self-sufficiency in lead. Costs of producing lead from various known resources were developed by the engineers to define the future availability of lead at various price levels. The study concluded that the United States can be self-sufficient and meet demands for lead for over 100 years at current rates of consumption. Seventy-five percent (60 million tons) of the available lead is estimated to be recoverable at prices under 20 cents per pound, and 90% of the total (72 million tons) is recoverable at prices under 50 cents.[12]

Research metallurgists at the Bureau of Mines laboratory in Reno, Nev., reported that promising results were obtained in applying chlorine-oxygen leaching to recover metals from complex sulfide concentrates which cannot be processed by smelting. Lead and silver in these concentrates were converted to insoluble forms and subsequently recovered from the leach residue by hot brine leaching and precipitation as lead chloride. High-purity lead was produced by fused-salt electrolysis.

Bureau metallurgists also developed a

method of processing galena concentrates without SO_2 or lead emissions by leaching with brine solution containing $FeCl_3$. Over 99% of the lead was converted to $PbCl_2$ in bench-scale tests, while sulfur was changed to the elemental form. The $PbCl_2$ was electrolyzed in a fused-salt cell to obtain lead metal meeting ASTM standards. Efforts to scale up the process and develop an efficient demonstration cell continued.

July	51,395	54,763	Total	603,024	663,870

Table 5.—Twenty-five leading lead-producing mines in the United States in 1974, in order of output

Rank	Mine	County and State	Operator	Source of lead
1	Buick	Iron, Mo	AMAX Lead Co. of Missouri	Lead ore.
2	Fletcher	Reynolds, Mo	St. Joe Minerals Corp	Do.
3	Ozark	do	Ozark Lead Co	Do.
4	Magmont	Iron, Mo	Cominco American, Inc	Do.
5	Brushy Creek	Reynolds, Mo	St. Joe Minerals Corp	Do.
6	Viburnum No. 29	Washington, Mo	do	Do.
7	Viburnum No. 28	Iron, Mo	do	Do.
8	Bunker Hill	Shoshone, Idaho	The Bunker Hill Co	Lead-zinc ore.
9	Lucky Friday	do	Hecla Mining Co	Lead ore.
10	Star Unit	do	do	Lead-zinc ore.
11	Indian Creek No. 32	Washington, Mo	St. Joe Minerals Corp	Lead ore.
12	Viburnum No. 27	Crawford, Mo	do	Do.
13	Burgin	Utah, Utah	Kennecott Copper Corp	Lead-zinc ore.
14	Idarado	Ouray and San Miguel, Colo.	Idarado Mining Co	Copper-lead-zinc ore.
15	Indian Creek No. 23	Washington, Mo	St. Joe Minerals Corp	Lead ore.
16	Leadville	Lake, Colo	American Smelting and Refining Co.	Lead-zinc and lead-zinc-copper ores.
17	Sunnyside	San Juan, Colo	Standard Metals Corp	Lead-zinc ore.
18	Austinville and Ivanhoe	Wythe, Va	The New Jersey Zinc Co	Zinc ore.
19	Balmat	St. Lawrence, N. Y.	St. Joe Minerals Corp	Do.
20	Camp Bird	Ouray, Colo	Federal Resources Corp	Lead-zinc ore.
21	Eagle	Eagle, Colo	The New Jersey Zinc Co	Zinc ore.
22	Ground Hog	Grant, N. Mex	American Smelting and Refining Co.	Do.
23	Dayrock	Shoshone, Idaho	Day Mines, Inc	Lead ore.
24	Pan American	Lincoln, Nev	St. Patrick Mining Co. Inc	Lead-zinc ore.
25	Bulldog Mountain	Mineral, Colo	Homestake Mining Co	Silver ore.

Table 6.—Refined lead produced at primary refineries in the United States, by source material

(Short tons)

	1970	1971	1972	1973	1974
Refined lead:[1]					
From primary sources:					
Domestic ores and base bullion	528,086	573,022	577,398	567,256	580,078
Foreign ores and base bullion	138,644	76,993	103,001	107,260	92,946
Total	666,730	650,015	680,399	674,516	673,024
From secondary sources	4,367	1,223	1,189	--	--
Grand total	671,097	651,238	681,588	674,516	673,024
Calculated value of primary refined lead (thousands)[2]	$209,220	$180,574	$204,528	$219,757	$303,265

[1] GSA metal is not included in refined lead production.

[2] Value based on average quoted price and excludes value of refined lead produced from scrap at primary refineries.

Table 7.—Antimonial lead produced at primary lead refineries in the United States

Year	Production (short tons)	Antimony content		Lead content by difference (short tons)			
		Short tons	Percent	From domestic ore	From foreign ore	From scrap	Total
1970	20,438	1,184	5.8	8,826	2,829	7,599	19,254

Total	538,590	600,945	Grand total	654,286	698,698
Grand total	654,286	698,698			

[1] Includes 1,065 tons of lead recovered in antimonial lead from secondary sources at primary plants in 1973 and 1,549 tons in 1974.

Table 12.—Lead consumption in the United States, by product

(Short tons)

Product	1973	1974	Product	1973	1974
Metal products:			Pigments—Continued:		
Ammunition	81,479	87,090	Pigment colors	16,963	17,336
Bearing metals	15,657	14,609	Other[1]	477	718
Brass and bronze	22,735	22,240			
Cable covering	43,005	43,426	Total	108,766	116,213
Calking lead	20,057	19,739			
Casting metals	7,220	7,507	Chemicals:		
Collapsible tubes	2,860	2,488	Gasoline antiknock additives	274,410	250,502
Foil	4,985	4,404	Miscellaneous chemicals	944	708
Pipes, traps, and bends	21,291	16,455			
Sheet lead	23,394	21,294	Total	275,354	251,210
Solder	71,770	66,280			
Storage batteries:			Miscellaneous uses:		
Battery grids, posts, etc.	365,557	391,479	Annealing	3,974	4,097
			Galvanizing	1,294	1,664
Battery oxides	403,890	460,402	Lead plating	744	498
Terne metal	2,658	2,300	Weights and ballast	20,848	21,418
Type metal	21,922	20,516			
			Total	26,860	27,677
Total	1,108,480	1,180,229	Other, unclassified uses	21,749	24,098
Pigments:			Grand total[2]	1,541,209	1,599,427
White lead	1,749	1,996			
Red lead and litharge	89,577	96,163			

[1] Includes lead content of leaded zinc oxide and other pigments.

[2] Includes lead which went directly from scrap to fabricated products.

Table 13.—Lead consumption in the United States, by month

(Short tons)

Month	1973	1974	Month	1973	1974
January	135,308	140,971	August	125,707	143,953
February	131,695	129,404	September	124,793	143,712
March	143,197	130,884	October	140,655	156,780
April	128,432	126,500	November	131,420	136,434

• Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Uganda and Egypt may produce lead, but available information is inadequate to make reliable estimates of output levels.

[2] Recoverable metal; lead content of concentrates for export plus lead content of domestic products (refined lead, antimonial lead, mixed bars, and other unspecified items).

[3] Recoverable metal.

[4] Recoverable metal; lead content of concentrates for exports plus lead content of domestic smelter products (refined lead, antimonial lead, and bismuth-lead bars).

[5] Data compiled from operating company reports of Tsumeb Corp. Ltd., South West Africa Co. Ltd., and South African Iron and Steel Industrial Corp. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine. Data from Tsumeb Corp. Ltd. are for calendar years; data from other companies are for fiscal years ending June 30 of the year stated.

[6] Figure comprises reported production of Tsumeb Corp. Ltd. and South West Africa Co. Ltd. plus an estimate for Rosh Pinah mine.

[7] Year beginning March 21 of that stated.

[8] Content of concentrates.

[9] Less than ½ unit.

[10] Contained in lead-copper concentrate.

Lime

By Avery H. Reed [1]

Lime output in 1974, including that for Puerto Rico, increased 2% to 21.6 million tons, a new annual record. Total value was a record $476.6 million, 29% above 1973.

Colorado Lien Co. planned to construct a 350-ton-per-day lime plant at Buena Vista, Colo. Dravo Lime Co. started construction of a lime plant at Maysville, Ky.; the $46 million, 3,000-ton-per-day plant will produce lime for use in removing sulfur from stack gases. Inland Steel Co. completed the first year of operation at the Indiana Harbor Works.

[3] Bureau of the Census.

DOMESTIC PRODUCTION

Lime producers in the United States and Puerto Rico sold or used a record 21.6 million tons, compared with 21.1 million tons in 1973. Sales of lime increased 2% to 14.7 million tons for a new annual record. Captive lime used by producers increased 4% to 7.0 million tons but was 4% below the 1971 record.

Output of quicklime increased 3% to 19.1 million tons. Production of hydrate decreased 3% to 2.6 million tons. Output of dead-burned dolomite increased 2% to 1.3 million tons but was 47% below the 1956 record. The number of plants decreased from 176 to 173, and the average output per plant increased from 120,000 to 125,100 tons per year.

Eight States, Ohio, Pennsylvania, Missouri, Texas, Michigan, Indiana, Alabama, and Illinois, each producing more than 1 million tons, accounted for 68% of the total output.

Leading producing companies were Marblehead Lime Co. with four plants in Illinois, one in Indiana, one in Michigan, and one in Pennsylvania; Mississippi Lime Co. in Missouri; Bethlehem Steel Corp. with one plant in New York and two in

---

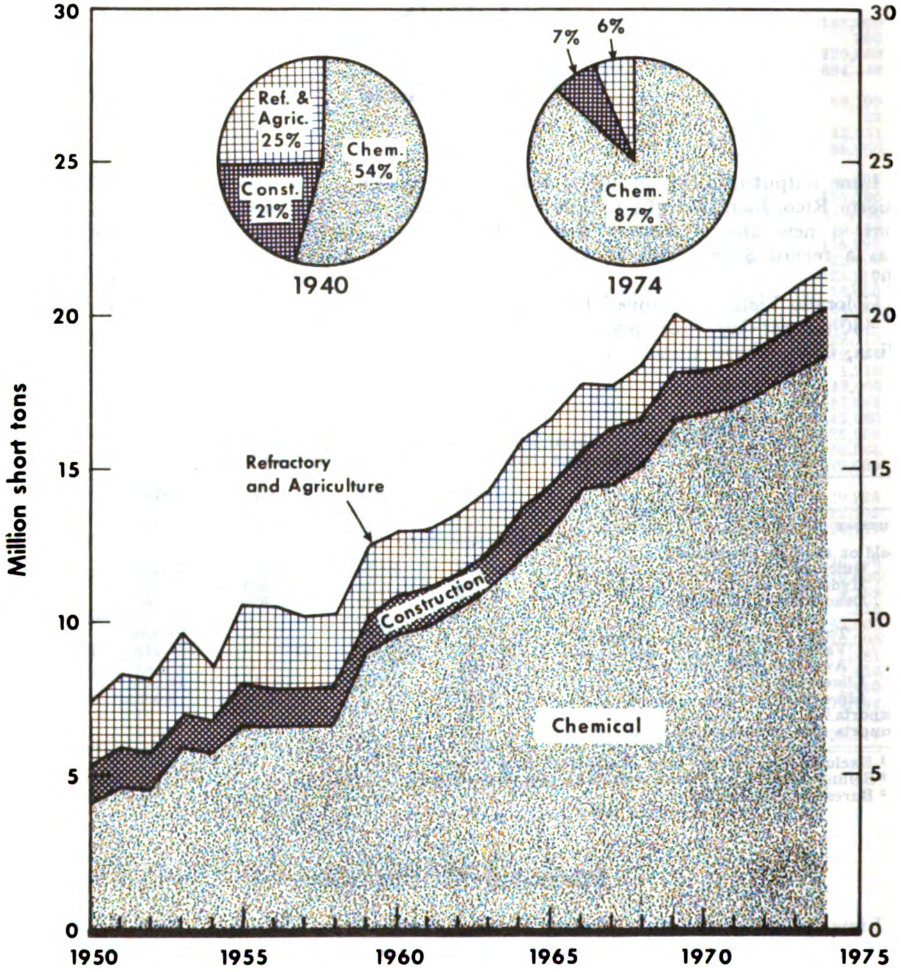

Figure 1.—Trends in major uses of lime.

Pennsylvania; Allied Chemical Corp. with a plant in Louisiana and a plant in New York; Martin-Marietta Chemicals with a plant in Alabama and a plant in Ohio; United States Gypsum Co. with a plant in Louisiana, a plant in Ohio, and a plant in Texas; United States Steel Corp. in Ohio; The Dow Chemical Co. with a plant in Michigan and a plant in Texas; Diamond Shamrock Corp. in Ohio; and Pfizer Inc. with plants in California, Connecticut, Massachusetts, and Ohio. These 10 companies, operating 26 plants, accounted for 41% of the total lime production.

The nine largest lime plants, each producing more than 400,000 tons per year, accounted for 27% of the total lime production. Forty-two plants produced more than 200,000 tons per year, and accounted for 69% of the total output.

Leading individual plants were Mississippi Lime's Ste. Genevieve plant, Marblehead's Buffington plant, Allied Chemical's Syracuse plant, United States Steel's Lorain plant, and Diamond Shamrock's Painesville plant.

CONSUMPTION AND USES

Lime was consumed in every State. Leading consuming States were Ohio, Pennsylvania, Indiana, Texas, Michigan, and Illinois, each of which consumed more than 1 million tons. These six States accounted for 58% of the total lime consumed.

Leading quicklime-consuming States were Ohio, Pennsylvania, Indiana, Michigan, Texas, and Illinois. These six States consumed more than 1 million tons each and accounted for 59% of the total quicklime consumed.

Leading hydrate-consuming States were Texas, Pennsylvania, Ohio, Illinois, and Louisiana, each of which consumed more than 100,000 tons. These five States accounted for 52% of the total hydrate consumed.

Lime sold by producers was used for chemicals, 81%; construction, 10%; refractories, 8%; and agriculture, 1%. Captive lime used by producers was 32% of the total, compared with 32% in 1973 and 34% in 1972. Captive lime was used mainly for alkalies, 37%; BOF steel furnaces, 24%; and sugar refining, 10%.

Leading individual uses were BOF steel furnaces, alkalies, water purification, refractories, and paper and pulp, which together accounted for 63% of the total consumption.

Lime for chemical and industrial use increased 4% to a record 18.8 million tons. Lime for refractory dolomite increased 2%. Lime for construction decreased 9%, and lime used in agriculture declined 22%.

Leading States for finishing lime were Ohio (41%), Nevada (23%), and Missouri (18%); those for mason's lime were Pennsylvania (21%), Wisconsin, and Ohio (13%). Lime for soil stabilization was used in Texas, which consumed 68% of the total, and other States.

Leading States for lime used in agriculture were Pennsylvania (34%), Maryland (21%), and Virginia (11%). Dead-burned dolomite was used in Ohio (58%), Pennsylvania (17%), Illinois (10%), and other States.

Of the main chemical and industrial uses, lime for BOF steel furnaces was consumed principally in Ohio (27%), Indiana (14%), Pennsylvania (14%), and Illinois (10%). Lime for alkalies was used mainly in Michigan (24%), New York (23%), and Louisiana (19%). Lime for water purification was used in Missouri (31%), Pennsylvania (16%), Texas (8%), Alabama (7%), and the remainder in other States. Lime used for paper and pulp, excluding regenerated lime, was consumed primarily in Alabama (36%), Texas (14%), and Virginia (10%). Lime for electric steel mills was used mainly in Missouri (16%), Texas (14%), Pennsylvania (14%), and Ohio (12%).

PRICES

The average value of lime sold or used by producers in 1974 was $22.02 per ton, an increase of 26% over the 1973 price of $17.42.

Values ranged from $21.51 for chemical lime to $25.11 for refractory dolomite, $25.33 for construction lime, and $28.46 for lime used in agriculture.

Values for quicklime sold ranged from $20.64 for chemical lime to $25.03 for dead-burned dolomite, $28.27 for lime used in agriculture, and $30.32 for construction lime, and averaged $21.22, an increase of 31% over the 1973 value.

Values for hydrated lime sold ranged from $22.15 for construction lime to $26.21 for chemical lime and $28.58 for lime used in agriculture, and averaged $25.66, an increase of 25% over the 1973 value.

[3] Includes Alaska, Vermont, and States indicated by symbol W.

FOREIGN TRADE

Exports of lime decreased 14% to 31,640 tons and were 54% below the 1968 record. Of the total exports, Canada received 67%, Mexico 14%, and Panama 3%. The remaining 16% went to 40 countries, listed in order of shipments: Philippines, Bahamas, Sweden, West Germany, Mozambique, Trinidad, Brazil, Republic of South Africa, Bermuda, New Zealand, El Salvador, Australia, Jamaica, the United Kingdom, Venezuela, Liberia, Nicaragua, India, Italy, United Arab Emirates, Angola, Guatemala, Haiti, Austria, Belize, the Netherlands Antilles, Indonesia, Saudi Arabia, Argentina, Honduras, Israel, Pacific Trust Islands, Bahrain, Colombia, Nigeria, Dominican Republic, Chile, Republic of South Korea, Surinam, and Japan.

Imports of lime increased 25% to a record 416,000 tons. Imports were mainly from Canada and entered the country principally through Buffalo and Detroit.

Table 7.—U.S. exports of lime

Year	Quantity (short tons)	Value (thousands)
1972	37,659	$1,242
1973	36,914	1,208
1974	31,639	1,516

WORLD REVIEW

Lime is produced all over the world, mainly in the heavily industrialized countries. Source materials are abundant. The United States, with 18% of the total, ranks second in world production following the U.S.S.R.

Australia.—Broken Hill Proprietary Co., Ltd., completed a 440-ton-per-day rotary kiln lime plant at Newcastle, New South Wales. Limestone for the plant is imported from Japan. The lime will be used in the company's BOF steel mill at Newcastle.

Canada.—During 1973 there were 24 active lime plants in Canada: 10 in Ontario, 4 in Quebec, 4 in Alberta, 3 in Manitoba, 2 in British Columbia, and 1 in New Brunswick. Of the 82 kilns in operation, 55 were vertical, 23 were rotary, 3 were rotary-grate, and 1 was vibratory-grate.

Companies active in Ontario were Algoma Steel Corp., Ltd., Allied Chemical Canada, Ltd., BeachiLime Ltd., Canadian Gypsum Co. Ltd., Cyanamid of Canada Ltd., Chromasco Corp. Ltd., Domtar Chemicals Ltd., Reiss Lime Co. of Canada Ltd., the Steel Co. of Canada Ltd., and Steeley of Canada (Holdings) Ltd.

Active companies in Quebec were Dominion Lime Ltd., Domtar Chemicals Ltd., Gulf Oil Canada Ltd., and Quebec Sugar Refinery.

Three companies were active in Alberta: Canadian Sugar Factories Ltd., Steel Brothers Canada, Ltd., and Summit Lime Works Ltd. Manitoba Sugar Co. Ltd. and Steel Brothers Canada, Ltd. produced lime in Manitoba. Columbia Lime Products Ltd. and Steel Brothers Canada, Ltd. operated lime plants in British Columbia. Havelock Lime Works Ltd. operated a lime plant in New Brunswick.

Germany, West.—West Germany ranked fourth in world lime output, with 10% of production.

Japan.—Japan produced 10% of world lime output, ranking third.

Poland.—Poland produced 7% of the world's lime and ranked fifth among countries.

United Kingdom.—Amey Roadstone Corp. completed a new lime plant at Cheddar. Capacity is 500 tons per day, and the kiln is fired by liquefied petroleum gas.

U.S.S.R.—The U.S.S.R. was the leading lime-producing country in the world, with 20% of the total, compared with 18% for the United States.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] Lime is produced in many other countries besides those listed. Mexico, Venezuela, and the United Kingdom are among the more important countries for which official data are unavailable.

[2] Excludes output by small producers.

[3] Less than ½ unit.

[4] Figures for 1972 and 1973 include production in Eritrea.

[5] Year ending June 30 of that stated.

TECHNOLOGY

The high price of fuels has resulted in increased interest in the use of preheaters for limekilns. Several installations have been made in Europe. Substantial savings in energy are claimed; compared with average kilns, heat requirements are reduced from 6 million to 4 million Btu per ton of lime.

Magnesium

By E. Chin [1]

World production capacity for magnesium was expected to increase substantially by 1980 owing to expansion of existing plants and construction of new ones. The Dow Chemical Co. announced plans for expanding its magnesium production capacity at Freeport, Tex., as well as constructing a new magnesium-metal facility. American Magnesium Co., at Snyder, Tex., was expected to complete installation of additional electrolytic cells by 1979. Northwest Alloys, Inc., was scheduled to begin magnesium production in late 1975 at Addy, Wash. In Japan, Showa Denko K.K. was constructing a facility to test a new thermal magnesium process, and in Norway, Norsk Hydro-Elektrisk A/S was constructing a pilot plant to test a new process for producing anhydrous magnesium chloride.

During 1974, there were four domestic price increases for magnesium metal. At the beginning of the year, the price of metal was 41.25 cents per pound. By yearend, it had risen to 75.00 cents per pound, with another announced price rise scheduled to take effect on January 1, 1975.

Domestic production of primary magnesium metal in 1974 was by the American Magnesium Co., Snyder, Tex.; The Dow Chemical Co., Freeport, Tex.; and NL Industries, Inc., Rowley, Utah. Data on U.S. production and shipments of magnesium metal are not published to avoid disclosing individual company confidential data.

Legislation and Government Programs.—In 1970, the Office of Preparedness removed magnesium metal from the list of strategic and critical materials, and the stockpile objective for magnesium was abolished. Under authority of Public Laws 90-604, 91-321, and 92-113, the General Services Administration (GSA) began disposing of all the magnesium remaining in the Government stockpile. A total of 20,981 short tons was sold during 1974 compared with 66,638 short tons sold in 1973.

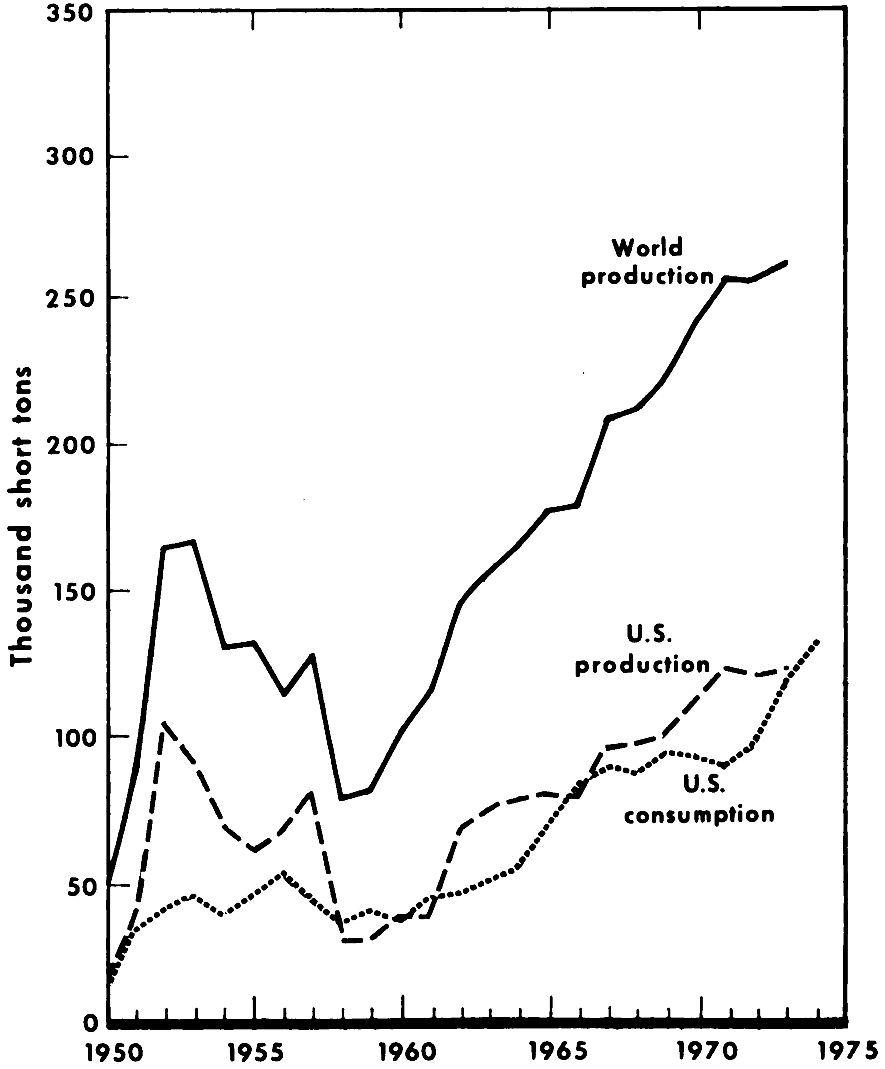

Figure 1.—U.S. and world production and U.S. consumption of primary magnesium.

DOMESTIC PRODUCTION

The Dow Chemical Co. announced an expansion program for producing magnesium metal at its plant in Freeport, Tex. Plant capacity was scheduled to be increased from 120,000 short tons per year to 135,000 short tons per year by 1978. Additionally, Dow Chemical announced its intention to construct a new magnesium-metal plant with a capacity of 50,000 short tons per year of metal. The site for the new facility was not announced, but completion is expected in 1980.

The electrolytic plant of American Magnesium Co., Snyder, Tex., had a capacity of 10,000 short tons of metal in 1974. The final addition of 20,000 tons was expected to be completed in 1979.

Northwest Alloys, Inc., a subsidiary of the Aluminum Co. of America (Alcoa), was constructing a magnesium facility at Addy, Wash. Startup of this plant, with an initial capacity of 24,000 tons per year of magnesium, was scheduled for 1975–76. The installation of additional capacity of 16,000 tons per year of metal was to be completed in 1980.

P Preliminary.

[1] Includes secondary magnesium content of both secondary and primary magnesium alloy ingot.

CONSUMPTION AND USES

Consumption of magnesium in the United States rose to 130,048 short tons in 1974. Magnesium was consumed in two broad categories: Structural products, such as castings and wrought products; and distributive or sacrificial applications, where advantage is taken of the chemical properties of the metal. Useful structural properties of magnesium include low specific weight, good machinability, hot formability, and high strength. The principal structural applications, which accounted for about 24% of the total use, were in aircraft, automotive, and other types of transportation equipment; materials handling; and power tools, such as powersaws and lawnmowers. The remainder of the consumption was for sacrificial uses, primarily alloying with other metals (especially aluminum), cathodic protection, production of nodular iron and desulfurization of steel, and as a reducing agent in the production of titanium, beryllium, and other metals.

PRICES

Throughout 1973, the quoted base price for primary magnesium pig and ingot in 10,000-pound lots, 99.8% magnesium f.o.b. plant, was 38.25 and 39.00 cents per pound, respectively. During 1974, the changes in the quoted price for magnesium metal were as follows:

Effective date	Cents per pound
January 1	41.25
March 11	47.00
May 1	55.00
July 1	65.00
August 1	75.00

Effective January 1, 1975, the price of magnesium will be raised 7 cents to 82 cents per pound.

STOCKS

Producer and consumer stocks of primary magnesium totaled 21,106 short tons as of December 31, 1974. Yearend stocks of primary magnesium alloy ingot were 1,677 tons. Stocks at yearend 1973 were 17,188 short tons of primary metal and 1,706 tons of alloy ingot.

FOREIGN TRADE

U.S. exports of magnesium increased from 39,585 short tons valued at $28.2 million in 1973 to 46,398 tons valued at $48.5 million in 1974. Shipments to Brazil, Canada, West Germany, Japan, Mexico, and the Netherlands accounted for 78% of the total U.S. magnesium exports. The remaining 10,358 tons was exported to 23 other countries. Approximately 96% of all the magnesium exported was in the form of primary metal and alloys.

Total magnesium imports for consumption increased from 3,325 short tons valued at $2.7 million to 5,305 tons valued at $5.2 million. Imports of waste and scrap accounted for 81% of the total imports of magnesium. West Germany, the largest U.S. source, contributed 22% of the metal imported. Receipts from the Netherlands and Canada constituted 21% and 16% of the magnesium imports, respectively. The remainder of U.S. imports, 2,181 tons, was contributed by 18 other nations.

WORLD REVIEW

World production of magnesium metal in 1974, excluding U.S. production, was 140,989 short tons. The U.S.S.R. produced 47% of the world magnesium output (excluding U.S. production), followed by Norway (30%), and Japan (7%). The remainder of the world production was by Canada, the People's Republic of China, France, and Italy.

World producers of magnesium in 1974 with annual capacities, processes, and plant locations were as follows:

Country	Company	Capacity (short tons)	Process	Plant location
Canada	Chromasco Corporation Limited.	12,000	Silicothermic	Haley, Ontario.
China, People's Republic of	NA	5,000	do	Ying-kou, Liaoning.
France	Société Générale du Magnesium (owned by Péchiney Ugine Kuhlmann S.A., 70%, and Société des Produits Azotes, 30%).	11,000	do	Marignac.
Italy	Societá Italiana per il Magnesio e Leghe di Magnesio.	12,000	do	Bolzano.
Japan	Furukawa Magnesium Co	7,000	do	Koyama.
	UBE Industries, Ltd	5,500	do	Yamaguchi.
Norway	Heroya Electrokemiske Fabbrikker A/S (subsidiary of Norsk Hydro-Elektrisk A/S).	44,000	I.G. Farben-industrie.	Heroya.
U.S.S.R	NA	50,000	Electrolytic	NA.
United States	American Magnesium Co	10,000		Snyder, Tex.
	The Dow Chemical Co	120,000	Dow cells	Freeport, Tex.
	NL Industries, Inc	45,000	Electrolytic	Rowley, Utah.

[1] Primary only.
[2] Secondary production was as follows, in short tons: 1972—5,612; 1973—8,936; and 1974 (preliminary)—11,990.
[3] The Dow Chemical Co. only.

Japan.—Showa Denko K.K. was constructing a pilot plant at Chickibu, Sartama, to test a new patented thermal magnesium process. The plant was planned to have a capacity of 440,000 pounds per year of magnesium. The startup date was not announced.

Norway.—Norsk Hydro-Elektrisk A/S reportedly developed a new process for producing anhydrous magnesium chloride. The process will be tested on an industrial scale at a plant being constructed at the Porsgrun Fabrikker facility at Heroya. If successful, this production will add 16,500 short tons to the existing metal capacity at Heroya.

TECHNOLOGY

A technique for the reduction of thorium dioxide using a magnesium-zinc alloy was described.[2] The present commercial method for the production of thorium metal involves the metallothermic reduction of thorium tetrafluoride with calcium in the presence of zinc chloride. Using a magnesium-zinc alloy as a reductant for thoria has the following potential economic advantages. Relatively inexpensive reagents are used for the metal and flux phases; and metal of acceptable quality can be produced with good yields.

The Nation's largest college ring maker began marketing a new alloy, called "siladium," for use in jewelry.[3] The alloy, which contains palladium, nickel, and magnesium, reportedly is tough and durable and does not tarnish.

A diving suit weighing 910 pounds was developed using magnesium castings that are sealed and then painted.[4] A constant pressure is maintained within the suit, thus eliminating the problems and dangers of normal compression and decompression. The suit was qualified for operating at a depth of 640 feet, but was tested at 2,000 feet.

Articles describing various techniques to produce ductile iron with magnesium were published.[5] Included in the discussions were the use of new magnesium alloy compositions, plunging techniques to allow the reacting magnesium to mix with the liquid iron, and the reduction of solids emissions.

Patents on the production of magnesium metal from dolomite and on the removal of magnesium chloride from carnallite were issued.[6]

Magnesium Compounds

By E. Chin [1]

World production of magnesite in 1974, excluding output in the United States, was 10,194,845 short tons, slightly more than that in 1973. Magnesite production in Austria, Greece, North Korea, the People's Republic of China, and the U.S.S.R. accounted for 73% of the world total.

The increasing worldwide trend toward greater production of magnesium compounds from seawater, well and lake brines, and dry lake deposits continued to exert competitive pressure on producers of magnesite. During 1974, two domestic companies, one using seawater as a raw material source and the other using well brines, completed expansions of production capacity for magnesium compounds. A Norwegian firm announced plans to produce magnesium hydroxide from seawater near the Arctic Circle.

Refractory magnesia and caustic-calcined and specified magnesias, sold or used by domestic producers in 1974, were 1.4% below those in 1973. However, the value of domestic shipments of magnesias rose 8% to $104,960,000 in 1974.

Exports of magnesite and magnesia were 62,000 tons in 1974, and as in 1970–73, the shipments were primarily to Canada. U.S. imports for consumption of processed magnesite in 1974 were 156,401 short tons, with Greece supplying 35% of the total.

DOMESTIC PRODUCTION

Magnesium hydroxide was produced from seawater and well brines by Barcroft Co., Basic Magnesia, Inc., Corhart Refractories, Co., Inc., The Dow Chemical Co., FMC Corporation, Harbison-Walker

---

[1] Physical scientist, Division of Nonferrous Metals.

Refractories, Kaiser Aluminum & Chemical Corp., Martin Marietta Chemicals, Merck & Co., Inc., Michigan Chemical Corp., and Morton Chemical Co. Most of the magnesium hydroxide produced was used in the production of magnesia for basic refractories. Producers of refractory magnesia were Basic, Inc., Basic Magnesia, Inc., Corhart Refractories Co., Inc., A. P. Green Refractories Co., Harbison-Walker Refractories, Kaiser Aluminum & Chemical Corp., and Martin Marietta Chemicals. Total production of refractory magnesia in 1974 was 779,554 tons.

Caustic-calcined magnesia was produced by Basic, Inc., Basic Magnesia, Inc., The Dow Chemical Co., Kaiser Aluminum & Chemical Corp., Martin Marietta Chemicals, and Michigan Chemical Corp. Total production of caustic-calcined magnesia was 224,518 tons in 1974. Merck & Co., Inc., Michigan Chemical Corp., and Morton Chemical Co. produced 13,065 tons of specified magnesia. The Dow Chemical Co., Giles Chemical Corp., and Philadelphia Quartz Co. produced 70,237 tons of magnesium sulfate (anhydrous and hydrous). During the year 11,150 tons of magnesium carbonate were produced by Merck & Co., Inc., Michigan Chemical Corp., and Morton Chemical Co.

Magnesium chloride was produced by American Magnesium Co., The Dow Chemical Co., FMC Corporation, Great Salt Lake Minerals & Chemicals Corp., Kaiser Aluminum & Chemical Corp., and NL Industries, Inc. Most of the magnesium chloride production was used for magnesium metal cell feed.

Domestic producers of magnesium compounds by raw material source, location, and capacity follow:

Raw material source and producing company	Location	Capacity (short tons MgO equivalent)
Magnesite: Basic, Inc	Gabbs, Nev	150,000
Lake brines:		
Great Salt Lake Minerals & Chemicals Corp	Ogden, Utah	100,000
Kaiser Aluminum & Chemical Corp	Wendover, Utah	50,000
Well brines:		
The Dow Chemical Co	Ludington, Mich	250,000
Martin Marietta Chemicals	Manistee, Mich	280,000
Michigan Chemical Corp	St. Louis, Mich	25,000
Morton Chemical Co	Manistee, Mich	5,000
Seawater:		
Barcroft Co	Lewes, Del	5,000
Basic Magnesia, Inc	Port St. Joe, Fla	100,000
Cohart Refractories Co., Inc	Pascagoula, Miss	40,000
The Dow Chemical Co	Freeport, Tex	100,000
FMC Corporation	Chula Vista, Calif	5,000
Harbison-Walker Refractories	Cape May, N.J	100,000
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif	150,000
Merck & Co., Inc	South San Francisco, Calif	10,000
Total		1,870,000

CONSUMPTION AND USES

In 1974, magnesia used in the production of basic refractories was 802,673 tons, slightly less than that in 1973. Consumption of caustic-calcined and specified magnesias for uses other than the production of refractory magnesia decreased significantly from that of 1973.

Magnesia was used as a fuel additive in burning heavy fuel at steam-generating plants to prevent corrosion and acid smut fallout. It also was used for stack gas scrubbing. As an additive to animal feed, magnesia prevents grass tetany in cattle and sheep, promotes increased egg laying, and increases the butterfat content of milk. In sugar cane processing mills, magnesia prevents scale formation in the evaporators. As an additive in rubber, magnesia is used to neutralize acidity, to keep the molds cleaner, and to improve the rubber cure rate. Other uses for magnesia are in chemicals, construction materials such as plaster and cement, cosmetics, electrical heating rods, fertilizers, medicinals and pharmaceuticals, and pulp and paper.

Other magnesium compounds were used in candy, wine, and water processing, in tannery applications, and in cosmetics and pharmaceuticals.

Table 2.—Magnesium compounds shipped and used in the United States

Year and product	Shipped and used	
	Quantity (short tons)	Value (thousands)
1973

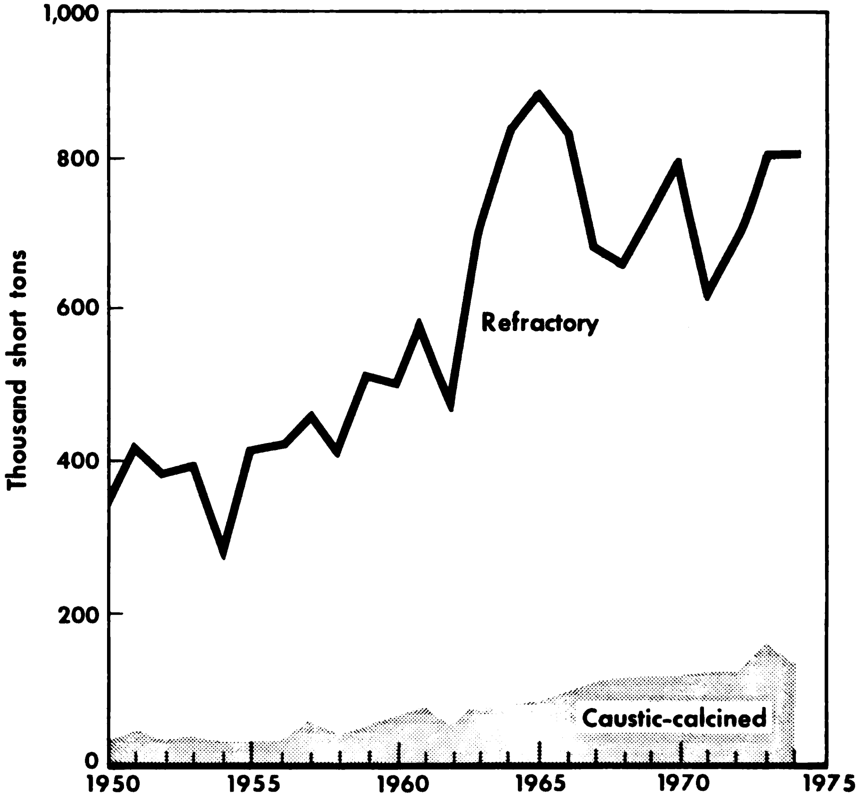

Figure 1.—Consumption and shipments of magnesia in the United States.

PRICES

The price for magnesia, natural, technical, heavy, 85% and 90% (bulk, carlot, truckload, f.o.b. Luning, Nev.) was quoted at yearend at $85 and $105 per short ton, respectively, according to the Chemical Marketing Reporter. Magnesia, technical, neoprene-grade, light, was quoted at $346 per ton (bags, carlot, truckload, works).

Prices throughout the year for magnesium carbonate, technical (bags, carlot, freight-equalized), remained the same as in 1973 at $0.16 per pound; prices for truckload quantities at $0.18 to $0.185 per pound were also unchanged. During the year, the price for magnesium hydroxide, NF, powder (drums, carlot, and truckload, works) was $0.30 per pound. Magnesium chloride, hydrous, 99%, flakes, bags, carlot, works, was quoted at $120 per ton.

The price for magnesium sulfate (technical, bags, mixed carlot, 10,000-pound minimum, works) was quoted at $0.05 per pound.

FOREIGN TRADE

Exports of dead-burned magnesite and magnesia in 1974 totaled 51,267 tons compared with 50,760 tons in 1973. Exports to the principal destination, Canada, were 39,649 tons, 7% lower than in 1973. However, shipments to the Netherlands and West Germany were substantially higher than in 1973.

Exports of magnesite, including crude, caustic-calcined, lump or ground, increased over exports in 1973 and totaled 10,733 tons. Deliveries to Australia, Canada, the United Kingdom, Venezuela, and West Germany accounted for over 62% of the exports in this class.

Imports of lump or ground caustic-calcined magnesia decreased 18% in 1974 to 8,990 tons. Receipts from India and Turkey accounted for over 86% of the imports in this class.

Imports of dead-burned and grain magnesia and periclase containing a maximum of 4% lime decreased 12% to 131,978 tons. Imports for the same class of material but containing over 4% lime increased from 8,956 tons in 1973 to 24,423 tons in 1974. Total imports of crude and processed magnesite decreased 2% from those in 1973 to 165,391 short tons.

Imports of specified magnesium compounds and compounds not specifically provided for, were valued at $2,107,000 in 1974 compared with $1,880,000 in 1973.

WORLD REVIEW

Greece.—During 1974, Financial Mining-Industrial & Shipping Corp. (FIMISCO) completed its dead-burned magnesite storage and shiploading facilities at Dafnopotamos, Mantoudi. Additionally, FIMISCO expanded its magnesite dressing plant at Paraskevorama from 100,000 tons to 250,000 tons, and doubled the output of its Moraitis facility to 70,000 tons per year. In June 1974, the Government approved plans to invest $15 million over the next 5 years in various related production facilities to boost its output of dead-burned magnesite.

Magnesite Mining Industrial and Commercial S.A. completed research and development studies to mine and process a magnesite deposit at Troupi, North Euboea. Construction at the site will begin in mid-1975, and includes an ore-dressing plant for 88,000 tons of concentrate per year and the installation of a 35,000-ton-per-year rotary kiln.

India.—Magnesite production in 1974

was 286,601 tons of which approximately 95% was from Tamil Nadu State. During 1973, consumption of magnesite was estimated as follows: Refractories, 188,100 tons; chemicals, 2,200 tons; fertilizers, 2,800 tons; and other, 450 tons.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria and Canada produce magnesite, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] Year beginning March 21 of that stated.

Important reserves of magnesite were estimated at 87.8 million tons,[3] as follows:

State	Occurrence	Tonnage (million short tons)	Grade percent
Tamil Nadu	Salem, Chalk Hills	47.7	43
Uttar Pradesh	Almora, Dewaldhar, and Agar-Girechchina	14.2	34–44
Do	Almora, Pungar Valley	13.4	NA
Do	Almora, Lahore Valley	2.8	43
Bihar	Singhbhum, Bhitardari	6.7	35
Rajasthan	Ajmer, Gaff-Sarupa	2.8	NA
Karnataka	Mysore, Dodkanya	.2	NA

NA Not available.

Israel.—During 1974, Dead Sea Works, Ltd., produced 16,500 tons of magnesium oxide and 29,700 tons of hydrochloric acid. The entire magnesium oxide output, valued at about $1 million, was exported, and the byproduct hydrochloric acid was shipped to the nearby Arad Chemical Industries, Ltd., plant to make high-grade phosphate acid. In 1975, the company planned to produce 38,500 tons of magnesia and 71,500 tons of hydrochloric acid. By 1976, the plant was expected to operate at full rated capacity (60,500 tons of magnesium oxide per year).

Norway.—Dresser Industries, Inc., and Norsk Hydro Elektrisk Kvaelstof A.S. disclosed plans to construct a $50 million seawater magnesia facility at Bodo, Norway. Construction of the plant, which will have a capacity of 220,000 tons of magnesia per year, was scheduled to begin in early 1975 and was expected to be completed by 1977.

---

[3] U.S. Embassy, New Delhi, India. State Department Airgram A-206, May 31, 1974, pp. 77–79.

Peru.—The Government of Peru received $42,000 of credit from the Andean Development Corp. to study the feasibility of establishing a metallurgical and chemical complex in the Bayovar district. Based on recent mineral finds, 3,500 million tons of brines containing 162 million tons of magnesium chloride and 19 million tons of potassium chloride have been outlined in the area in addition to 38,000 million tons of phosphate material.

Turkey.—Kütahya Manyezit Isletmeleri A.S. of Ankara (Kumas) was constructing a dead-burned magnesite plant near Kütahya in west-central Turkey. The plant was designed to produce 70,000 to 80,000 tons per year of refractory-grade magnesia and was expected to be onstream in early 1976. Feed material for the plant will come from the company's magnesia operations at Kütahya and will be supplemented by high-quality magnesite from private operators in the Eskisehir area.

Seawater magnesia production facilities and capacities throughout the world by country follow:

Country	Location	Company	Capacity (short tons MgO)
Canada	Aguathuna, Newfoundland	Lundrigan's Ltd	80,000
Ireland	Dungarvan, Waterford	Pfizer Chemical Corp	75,000

Total			2,169,000

[1] Seawater production facilities appear in tabulation shown in "Domestic Production" section of this chapter.

TECHNOLOGY

The domestic magnesium resource position was reviewed in a Geological Survey publication.[3] U.S. and world resources of magnesium were characterized as unlimited in brines and seawater, and large in bedrock.

An extensive review of magnesium discussed the production of metal, alloys and compounds, international trade, uses, and prices.[4] Future trends in demand and production for the metal and compounds were included.

Literature on the availability of magnesium oxide throughout the world was reviewed.[5] Production of crude magnesite was estimated to have grown from about

Manganese

By Gilbert L. DeHuff[1]

In 1974, there was no U.S. production of manganese ore, concentrate, or nodules, containing 35% or more manganese, and 1974 was the first year since 1880 or earlier that no shipments were recorded. Imports of ferromanganese again increased above the record level of the previous year, but imports of manganese ore declined. Both consumption of ore and production of ferromanganese again dropped. The General Services Administration (GSA) continued its sales of surplus manganese stockpile items, particularly metallurgical ore and high-carbon ferromanganese. Prices for ore, alloys, and metal increased during the year under pressure of high demand; increased freight, environmental and energy costs; and inflation.

Both domestic and foreign interests, working together as a rule within different consortia, intensified their investigations of the possibilities for mining deep sea manganese nodules, but only the group headed by Deepsea Ventures Inc. included the recovery of manganese in its initial plans. Deepsea Ventures progressed to the point that it publicly announced that it was developing and evaluating, preliminary to mining, a specified area of nodule-bearing Pacific Ocean floor, claiming exclusive rights to the deposit.

Legislation and Government Programs.—Cumulative sales of stockpiled manganese items for the calendar year, as reported by GSA, were as follows in short tons (gross weight): Synthetic dioxide, 10,678; type B chemical ore, 1,000; metallurgical ore, 474,765 of stockpile grade and 23,420 of nonstockpile grade; and high-carbon ferromanganese, 233,968.

Late in December, GSA announced that it would continue to offer metallurgical-grade manganese ore for sale on a negotiated basis. Deliveries were to be limited to 750,000 short tons per fiscal year. Terms, conditions, pile numbers, locations, quantities, and analyses were contained in Solicitation of Offers ORES–233, which replaced Solicitation of Offers ORES–170 issued July 31, 1972. At the same time, 111,586 tons of type A and 63,238 tons of type B chemical-grade ore were offered for sale on a negotiated basis under Solicitation of Offers ORES–232. The type B ore was limited to an annual disposal rate of 10,000 tons, but there was no limit for type A ore. Early in October, GSA offered 118,451 tons of natual battery ore for sale on a negotiated basis under terms contained in Solicitation of Offers ORES–225. The maximum rate of disposal was placed at 15,000 tons per fiscal year.

Manganese stockpile inventory changes in calendar year 1974 consisted of the following: Synthetic dioxide decreased 6,400 short tons to 8,138 tons; type A chemical ore increased 47 tons to 146,633 tons; type B chemical ore decreased 1,174 tons to 99,497 tons; metallurgical ore, stockpile grade, decreased 1,045,896 tons to 6,203,138 tons; metallurgical ore, nonstockpile grade, decreased 9,931 tons to 1,367,951 tons; high-carbon ferromanganese dropped 449,481 tons to 662,044 tons; and electrolytic metal was down 3,957 tons to 14,196 tons.

r Revised.

DOMESTIC PRODUCTION

There was neither production nor shipment of manganese ore, concentrate, or nodules, containing 35% or more manganese, in the United States in 1974. This was the first year since at least 1880 that no shipments of manganese ore were recorded.

Ferruginous manganese ore containing 10% to 35% manganese was produced and shipped in New Mexico, and shipments continued from mine or mill stockpiles on the Cuyuna Range of Minnesota. As in 1973, total shipments of ferruginous manganese ores or concentrates were greater than those of the preceding year. Manganiferous iron ore containing 5% to 10% manganese was neither produced nor shipped in either 1974 or 1973. Manganiferous zinc residuum continued to be recovered from New Jersey zinc ores.

Table 2.—Manganese and manganiferous ore shipped [1] in the United States, by State
(Short tons)

Type and State	1973		1974	
	Gross weight	Manganese content	Gross weight	Manganese content
Manganese ore (35% or more Mn, natural):				
Montana	239	125	--	--
Total	239	125	--	--
Manganiferous ore:				
Ferruginous manganese ore (10% to 35% Mn, natural):				
Minnesota	170,971	21,526	225,560	28,744
New Mexico	32,084	4,171	47,348	6,060
Total [2]	203,055	25,697	272,908	34,804
Value manganese and maganiferous ore	$1,531,390	--	$2,323,254	--

[1] Shipments are used as the measure of manganese production for compiling U.S. mineral production value. They are taken at the point at which the material is considered to be in marketable form for the consumer. Besides direct-shipping ore, they include, without duplication, concentrate and nodules made from domestic ores.

[2] There were no shipments of manganiferous iron ore containing 5% to 10% Mn, natural.

CONSUMPTION, USES, AND STOCKS

In the production of raw steel (ingots, continuous- or pressure-cast blooms, billets, slabs, etc., and including steel castings), consumption of manganese as ferroalloys, metal, and direct-charged ore was 13.3 pounds per short ton of raw steel produced. Of this total, 11.5 pounds was ferromanganese; 1.4 pounds, silicomanganese; 0.05 pound, spiegeleisen; 0.25 pound, manganese metal; and 0.1 pound manganese ore (containing 35% or more manganese). The comparable 1973 total, on the same basis, was 12.9 pounds with ferromanganese at 11.1, silicomanganese at 1.3, spiegeleisen at 0.05, metal at 0.25, and ore at 0.2. In addition to the aforementioned consumption of manganese in 1974, there was consumed per short ton of raw steel produced approximately 1.2 pounds of manganese contained in manganese ore used in making pig iron or equivalent hot metal. The comparable figures for 1973 and 1972 were 1.1 and 1.2 pounds, respectively.

Large capital expenditures for pollution control programs to meet environmental standards continued to be reported by the producers of manganese ferroalloys and metal. High energy, labor, and material costs encountered by the industry were further increased by the significant added costs of operation of the pollution-control equipment. Energy shortage problems continued to be experienced. In August, the Rockwood, Tenn., plant of the Roane Electric Furnace Division of Woodward Corp. was purchased by Engelhard Minerals & Chemicals Corp. Marketing of the products will be by the latter's Philipp Brothers Division. Operations of Tenn-Tex Alloy Corp. of Houston after July 1 were under a 6-year lease to Union Carbide Corp., with all production going to the latter.

Table 3.—Consumption and industry stocks of manganese ore[1] in the United States

(Short tons)

	Consumption		Stocks Dec. 31, 1974
	1973	1974

[1] Virtually all electrolytic.

Electrolytic Manganese Metal.—All of the manganese metal produced domestically was electrolytic, and it is certain that virtually all of that imported was electrolytic metal. Virtually all of the metal consumed was electrolytic metal, but it is probable that some low-carbon ferromanganese and some manganese-aluminum additives were erroneously reported by consumers as manganese metal. The metal used to make manganese-aluminum additives is included in table 4 under the "Alloys (excludes alloy steels and superalloys)" category. The additives are not knowingly included in the table, it being desired to obtain consumption at the metal rather than the additive level of the usage cycle. Production of electrolytic metal in 1974 was 27,033 short tons, compared with 26,175 tons in 1973, and was by the same three plants of the same three companies: Foote Mineral Co., New Johnsonville, Tenn.; Kerr-McGee Chemical Corp., Hamilton (Aberdeen), Miss.; and Union Carbide Corp., Marietta, Ohio. Kerr-McGee Corp. was increasing its annual capacity from 8,200 to 9,300 tons with completion scheduled for 1975. After completion of a tender offer in September, Newmont Mining Corp. announced that it had increased its ownership of Foote Mineral Co. to 84% of Foote's outstanding voting shares.

Ferromanganese.—The Johnstown, Pa., plant of Bethlehem Steel Corp. was the only producer of ferromanganese in blast furnaces in 1974. Electric furnaces were used to produce ferromanganese by six other companies in seven plants: Airco Alloys Div., Airco Inc., Calvert City, Ky.; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Div. of Woodward Corp., Rockwood, Tenn. (plant acquired by Engelhard Minerals & Chemicals Corp. in August 1974 and operated afterwards as Roane Electric Furnace Co.); Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W. Va., Marietta, Ohio, and Portland, Oreg. Fused salt electrolysis continued to be the method used by the Chemicals unit of Diamond Shamrock Corp., Kingwood, W. Va., to make low-carbon ferromanganese sold under the trade name of Massive Manganese. The company planned to double Kingwood's capacity to 17,000 short tons per year by the end of 1975. Cost was estimated to be between $5 million and $6 million, of which more than $1 million will be for pollution-control equipment. U.S. shipments of ferromanganese from furnaces totaled 574,000 short tons compared with 779,000 tons in 1973.

The production reported in the various tables of this chapter is net production; that is, the quantity of ferromanganese produced for shipment outside the producing establishment. It does not include the remelt—fines, offgrade, or other ferromanganese output of the furnace—that was fed back to the furnace or lost in the plant, and which is included in gross production figures reported by the furnace operator.

Table 5.—Ferromanganese and silicomanganese produced in the United States and manganese ore[1] consumed in their manufacture

Year	Production				Manganese ore[1] consumed (gross weight, short tons)			
	Ferromanganese							
	Gross weight (short tons)	Manganese content		Silicomanganese (gross weight short tons)	Foreign[2]	Domestic[2]	Per ton of ferromanganese made[3]	Per ton of ferromanganese and silicomanganese made[3][4]
		Percent	Short tons					
1970 ---	835,463	78.5	655,436	193,000	2,098,210	1,216	2.4	2.0
1971 ---	759,896	78.6	597,205	165,000	1,820,408	7,033	2.4	1.9
1972 ---	800,723	78.3	627,358	153,000	1,896,483	25,620	2.3	2.0
1973 ---	683,075	78.8	538,119	184,000	1,648,806	25,912	2.4	1.9
1974 ---	544,361	78.0	424,405	196,000	1,348,425	55,822	2.5	1.8

[1] Containing 35% or more manganese (natural).
[2] Includes ore used in producing silicomanganese and metal.
[3] Includes ore used in producing silicomanganese.
[4] Ratio of ore consumed to ferromanganese produced if silicomanganese is considered a special grade of ferromanganese.

Table 6.—Manganese ore used in producing ferromanganese, silicomanganese, and manganese metal in the United States in 1974, by source of ore

Source	Gross weight (short tons)	Mn content, natural (percent)
Domestic [1]	55,822	52
Foreign:		
Africa	407,777	48
Australia	121,150	50
Brazil	454,050	48

Unidentified	114,517	--
Total	1,404,247	48

[1] Most, if not all, from U.S. Government surplus stockpile disposals.

Silicomanganese.—Production of silicomanganese in the United States increased to 196,000 short tons from the 184,000 tons of the previous year. This is net production produced for shipment, and does not include silicomanganese produced for use as an intermediate in the same plant for the production of medium- or low-carbon ferromanganese. Silicomanganese shipments from furnaces were 192,000 tons, compared with 196,000 tons in 1973. In 1974, seven companies used eight plants to produce silicomanganese for shipment: Airco Alloys Div., Airco Inc., Theodore (Mobile), Ala.; Interlake Inc., Beverly, Ohio; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Div. of Woodward Corp., Rockwood, Tenn. (plant acquired by Engelhard Minerals & Chemicals Corp. in August and operated afterwards as Roane Electric Furnace Co.); Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W. Va., Marietta, Ohio, and Portland, Oreg. End-use consumption of silicomanganese, that is consumption outside the ferroalloy plants, was 15.9% that of ferromanganese, compared with 14.2% in 1973. The increases in this ratio of the last 2 years, a reversal of the declining trend evidenced since 1965, may be attributed in large part to an acute shortage of ferrosilicon ordinarily used for silicon additions.

Spiegeleisen.—The New Jersey Zinc Co. continued to produce spiegeleisen in electric furnaces at Palmerton, Pa.

Pig Iron.—A total of 465,000 short tons of manganese-bearing ores containing over 5% manganese (natural) was consumed in the production of pig iron (or its equivalent hot metal). Domestic sources supplied 256,000 tons, of which 171,000 tons was manganiferous iron ore containing 5% to 10% manganese, and 85,000 tons was ferruginous manganese ore containing 10% to 35% manganese. Foreign sources supplied 209,000 tons, of which 1,000 tons was manganiferous iron ore, and 208,000 tons was manganese ore containing 35% or more manganese.

Battery and Miscellaneous Industries.—The ore reported in table 3 includes that consumed in making synthetic manganese dioxide by either electrolytic or chemical means, but it does not include consumption of the synthetic dioxide. Although some synthetic dioxide is used for chemical purposes, most of it is used in the manufacture of dry-cell batteries, particularly for the manganese-alkaline type, premium or heavy-duty Leclanché (manganese dioxide-ammonium chloride-zinc) cells, and as a blend with natural ore in ordinary Leclanché cells.

The domestic ore and much of the foreign ore used for chemical and miscellaneous purposes did not meet national stockpile specification P–81–R for chemical-grade ore.

Kerr-McGee Corp. was engaged in increasing the annual capacity of its Henderson, Nev., plant from 8,700 to 12,000 short tons of electrolytic synthetic manganese dioxide; completion was scheduled for 1975.

PRICES

Strong world demand, increased freight, environmental, and energy costs, and inflation, all contributed to increases in manganese prices in 1974.

Manganese Ore.—All manganese ore prices are negotiated, dependent in part on the characteristics and quantity of ore offered, delivery terms, and fluctuating ocean freight rates. Trade journal quotations reflect the paper's evaluation of the market. American Metal Market quotations for metallurgical-grade manganese ore began the year at 80 to 93 cents, nominal, per long-ton unit, c.i.f. eastern seaboard and Gulf ports, for a manganese content of 46% to 48%; $1.00 to $1.10, nominal, same basis, for a content of 48% to 50% manganese. In July these quotes were increased to 80 to 95 cents, nominal, and $1.05 to $1.15, nominal, respectively. Metals Week's quotation for the higher grade ore was $1.05 to $1.15 for the first half of the year, and $1.10 to $1.18 until early December when it was increased to $1.18 to $1.38. At mid-month it was marked up to $1.38 to $1.42 per long ton unit, c.i.f. U.S. ports, and identified as the producer agent and dealer price for metallurgical ore of low impurity, minimum 47% to 48% manganese. This quote was continued to the end of the month.

Manganese Alloys.—The price of most domestically produced standard high-carbon ferromanganese having a manganese content of 78% was $200 per long ton, f.o.b. producer plant or shipping point, until Government price controls were removed in March. However, during at least part of this period, some domestic production sold for $250 per long ton. Upon removal of the controls, which had been instituted in 1973, the price became $270 per long ton. Three subsequent increases found the price at $400 per long ton at the beginning of November. By that time, the Metals Week quotation for imported alloy of the same grade had reached $450 to $460 per long ton of alloy, having been $190 to $197 at the beginning of the year. The quotes for the imported material were unchanged for the balance of 1974, but the producer price was increased to $440 on December 27.

Manganese Metal.—The price of standard or comparable grades of electrolytic manganese metal increased several times during the year, going from a dual price of 33.25 to 37.25 cents per pound that was effective January 1 to a price of 54 cents per pound effective November 18 through the end of the year. These prices continued to be f.o.b. producer plant for shipments of 30,000 pounds or more.

FOREIGN TRADE

Exports of ferromanganese were 7,011 short tons valued at $2,203,957, compared with 8,574 tons valued at $2,136,917 in 1973. Of the 1974 quantity, Canada took 3,638 tons; Taiwan, 1,178 tons; Sweden, 416 tons; the Netherlands and West Germany, each 414 tons; the Dominican Republic, 244 tons; Mexico, 224 tons; Venezuela, 184 tons; Colombia, 112 tons; Brazil and the Republic of South Africa, each 44 tons; Guatemala, 40 tons; France, 25 tons; and five other countries, smaller quantities. Exports classified as "manganese and manganese alloys, wrought or unwrought, and waste and scrap" totaled 2,318 tons valued at $2,118,803, compared with 4,660 tons valued at $3,108,688 in 1973. This classification includes electrolytic manganese metal and manganese-copper alloys, but it does not include ferromanganese. Exports of ore and concentrate containing more than 10% manganese totaled 223,088 tons valued at $13,656,462, compared with 57,448 tons valued at $4,535,463 in 1973. Of the total, large quantities having relatively low average values were distributed as follows: Spain, 62,000 tons; Canada, 57,000 tons; Mexico, 29,000 tons; the Netherlands, 21,000 tons; and Norway, 19,000 tons. For the most part, these tonnages appear to have been metallurgical ore obtained from GSA sales of Government surplus stocks.

The average grade of imported manganese ore in 1974 was 48% manganese, as in 1973. Brazil supplied 38% of this ore in 1974; Gabon, 25%; and Australia, 19%. Imports of manganiferous ore (more than 10% but less than 35% manganese) totaled 1,717 short tons, of which 1,653 tons came from Morocco and 64 tons came from Mexico. The tonnages from each country had an average manganese content of 34%.

Ferromanganese imports for consumption again exceeded the record high of the previous year. France and the Republic of South Africa continued to be the principal suppliers. Both are countries in which a U.S. company has a substantial interest in a ferromanganese produced. Silicomanganese imports for consumption totaled 67,751 short tons containing 44,720 tons of manganese. Sources and tonnages (gross weight) were as follows: Norway, 23,666; Japan, 18,616; Spain, 8,205; Yugoslavia, 5,622; the Republic of South Africa, 3,102; Brazil, 2,480; the Netherlands, 1,654; Sweden, 1,644; the Republic of Korea, 1,378; Canada, 992; West Germany, 392. Imports for consumption classified as unwrought manganese metal, except alloys, and metal waste and scrap, totaled 2,506 short tons, compared with 2,452 tons in 1973 and 4,121 tons in 1972. Of the 1974 total, 2,123 tons came from the Republic of South Africa, 209 tons from Japan, and 174 tons from Canada. A small quantity (40 pounds) of high unit value ($7.45) came from West Germany.

Table 7.—U.S. imports [1] of manganese ore (35% or more Mn), by country

Country	1973			1974		
	Gross weight (short tons)	Mn content (short tons)	Value (thousands)	Gross weight (short tons)	Mn content (short tons)	Value (thousands)
Australia	123,813	61,458	$2,760	233,454	114,038	$8,136
Brazil	629,833	299,402	15,767	463,763	222,000	15,105
Canada	611	354	51	--	--	--
Gabon	393,037	196,114	10,007	302,530	150,117	12,712
Ghana	38,965	18,601	1,076	9,850	4,531	425
Mexico	105,019	41,206	2,616	39,021	16,431	1,018

[r] Revised.

Imports for consumption classified as "manganese compounds, other" totaled 3,086 short tons, compared with 4,355 tons in 1973 and 7,937 tons in 1972. The sources, gross weights, and values per pound in 1974 were as follows: Japan, 2,194 tons (28 cents); Belgium, 713 tons (28 cents); the United Kingdom, 145 tons (14 cents); West Germany, 29 tons (71 cents); the Republic of South Africa, 5 tons (34 cents); and the Netherlands, less than 1 ton ($3.61). The imports from Japan and Belgium appear to have consisted largely, if not entirely, of synthetic manganese dioxide. Imports of manganese sulfate were 20 tons in 1974, 40 tons in 1973, 42 tons in 1972, and 22 tons in 1971. Except for 2½ tons from West Germany in 1972 and in 1971, all of these sulfate imports came from Belgium.

Tariffs.—The duty on manganese ore from most nations remained suspended, while the statutory rate continued to be 1 cent per pound of contained manganese and continued to apply to ore from the U.S.S.R. and the People's Republic of China. The respective rates of duty for metal and the principal manganese ferroalloys continued as shown in the following tabulation:

Material	TSUS No.	Rate of Duty	
		Most Favored Nation	Statutory
Metal	632.32	1.5¢/lb + 10% ad valorem [1]	1.875¢/lb + 15% ad valorem [1]
Ferromanganese:			
High carbon	607.37	0.3¢/lb Mn	1.875¢/lb Mn
Medium carbon	607.36	0.46¢/lb Mn	1.875¢/lb Mn
Low carbon	607.35	0.3¢/lb Mn + 2% ad valorem	1.875¢/lb Mn + 15% ad valorem
Silicomanganese	607.57	0.46¢/lb Mn + 3.5% ad valorem	1.875¢/lb Mn + 15% ad valorem

[1] Duty on metal waste and scrap temporarily suspended through June 30, 1975.

WORLD REVIEW

Of the numerous organizations working toward the mining of manganese nodules from the ocean floor, only the consortium headed by Deepsea Ventures, Inc., included manganese recovery in its initial exploitation plans. All others were focusing their attention on recovery of only the contained nickel, copper, and cobalt for the start of operations.

In May, Tenneco Inc., the parent company of Deepsea Ventures, announced that it had signed an agreement with three Japanese trading firms—Nichimen Co., Ltd., C. Itoh & Co., Ltd., and Kanematsu-Gosho Ltd., all of Tokyo—that was expected to lead to a joint venture to assess a selected Pacific deep sea deposit, test the mining and processing systems, and test the market for the manganese, nickel, copper, and cobalt products to be recovered. The Japanese group later organized as Japan Manganese Nodule Development Co. and included minor participation by two other firms: Hitachi Shipbuilding and Engineering Co.; and Japan Metals and Chemicals Co.[2] Projected development and evaluation will involve $20 million over a period of up to 3 years. Total expenditures are expected to reach approximately $200 million before commercial production can be achieved by Deepsea Ventures, the operating company.

In November or earlier, United States Steel Corp. through its wholly-owned subsidiary, Essex Iron Co.; and the Belgian mining firm, Union Minière, S.A., through its wholly-owned Maryland subsidiary, Union Mines Inc., joined the venture by acquiring options to buy equity interests. If all outstanding options are exercised, these two companies and the Japanese group will each have equal participation of 23.75%. The remaining 28.75% will be held by the present owners—now 90% Tenneco and 10% individual U.S. citizens. Deepsea Ventures, in a November 14 letter addressed to the Secretary of State, gave public notice that it had discovered, taken possession of, and was engaged in developing and evaluating, preliminary to mining, a seabed deposit of manganese nodules lying in the North Pacific between longitudes 124°20'W and 127°46'W, and between latitudes 14°16'N and 15°44'N, at depths between 7,500 and 16,000 feet. This rectangular area is a bit more than a third of the distance between Hawaii and Colombia, and approximately 1,500 miles south of San Francisco.

Exclusive rights to the deposit were claimed in the belief that such claim was valid under existing international law. Deepsea further requested diplomatic protection and protection of its investment. Initial plans called for recovering approximately 1.5 million wet short tons of nodules per year from the deposit, from which approximately 280,000 short tons of high-purity manganese metal, 12,500 tons of nickel, 10,000 tons of copper, and 2,370 tons of cobalt were expected to be recovered. Possible later expansion of operations to an annual recovery rate of approximately 4.4 million wet short tons per year of nodules would be dependent on market conditions.[3]

---

[2] American Metal Market. V. 81, No. 225, Nov. 19, 1974, p. 18.

[3] Congressional Record. Dec. 5, 1974, pp. E6970–E6971.

Early in the year, Kennecott Copper Corp. announced a 5-year, $50 million research and development program having for its objective the commercial recovery of approximately 3 million dry tons of nodules per year from the Pacific Ocean floor, possibly by 1980–81. Kennecott, with a 50% interest, will manage the program. Rio Tinto-Zinc Corp. Ltd., London, has a 20% interest. Consolidated Gold Fields Ltd., London; Mitsubishi Corp., Tokyo; and Noranda Mines Ltd., Toronto, each have a 10% interest. As with Deepsea Ventures in its activities, it has been estimated that Kennecott has already spent approximately $20 million over a 10-year period.

Costs for a 3-million-ton-per-year nodule-processing plant in the United States to recover nickel, copper, and cobalt supplied by two mining units with a total design capacity of 4 million tons of nodules per year were estimated by British members of the Kennecott consortium. Total investment was estimated to range from a low of $350 million to a high of $650 million; annual operating costs including depreciation, from a low of $115 million to a high of $170 million. It was doubted that commercial production could begin before 1980. Admitting the difficulty of predicting metal prices for that year, and recognizing taxation uncertainties, it was nevertheless concluded that nodule operations appeared to be competitive with potential nickel laterite deposits, with increasing energy costs favoring the nodule operations. It was further concluded that great profitability (implied by some proponents in the past) of first-generation plants was unlikely; that taxation and royalties should be no more than for land-based mining operations; and that accelerated depreciation or some other form of tax relief might be necessary in the early years. Political and legal problems remained the greatest uncertainty facing any commercial operation.[4]

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Cuba and the Territory of South-West Africa also may have produced manganese ore and/or manganiferous ore but available information is inadequate to make reliable estimates of output levels. Low grade ore not included in this table has been reported as follows in short tons: Czechoslovakia (about 17% Mn): 1972—nil; 1973—1,100; 1974—1,100; Malaysia (grade unspecified but apparently a manganiferous ferruginous ore): 1972—nil; 1973—31,246; 1974—93,985; Romania (about 22% Mn): 1972—143,000; 1973—155,000; 1974—155,000; Republic of South Africa (15–30% Mn in addition to material listed in table): 1972—112,058; 1973—73,333; 1974—98,769.

[2] Estimated on the basis of reported contained manganese.

[3] Exports.

[4] Source: The National Economy of the U.S.S.R., Central Statistical Administration, Moscow. Grade represents the annual average obtained from reported metal contents for the gross weights shown in the table.

[5] Official publications list no production during first 3 months of 1974. Information for subsequent months is not available but owing to internal political problems, it is likely that production, if any, was quite modest.

[6] Of total 1972 output, 57.6% graded below 35% Mn and of total 1973 output, 64% graded below 35% Mn, with the balance in each year grading 35% Mn to 48% Mn or more. Comparable 1974 production breakdown not available, but export figures for April to October of that year give 78% below 35% Mn.

[7] Iranian calendar year beginning March 21 of year stated.

[8] Japanese imports from New Hebrides.

Argentina.—Manganese ore produced in 1973 had an average manganese content of 28%. Imports of manganese ore and concentrates were 62,000 short tons in 1973, compared with 46,000 in 1972. Production of rhodochrosite, mined as a semiprecious stone rather than an ore, was 131 tons in 1973 and 149 tons in 1972; exports were 98 and 128 tons in 1973 and 1972, respectively.

Australia.—The deposit of manganese ore at Groote Eylandt, Northern Territory, has been proved over an area of 20 square miles, and reserves have been estimated by the operating company, Groote Eylandt Mining Co. Ltd., to be on the order of 300 million tons with an average grade of roughly 48% manganese. This tabular deposit is of lower Cretaceous age, flat lying or gently dipping, and basically pisolitic or lateritic in character with evidence of weathering and redeposition. It is from 1.5 to 50 feet thick, although the portions being mined in 1974 were approximately 10 to 13 feet in thickness. The ore, which grades up to 55% manganese, is essentially of two types: "Pisolitic ore" averaging about 44% manganese in the ground, and "massive ore" averaging about 48% to 50%. Comparatively unconsolidated silts and sands, and in a few areas a manganiferous ferruginous laterite, cover the deposit. Similar unconsolidated sands, silts, clays, claystones, and soft sandstones underlie it. In 1974, almost all the ore was beneficiated; the stripping ratio was approximately one overburden to two ore. Some selective mining was practiced. Beneficiation consisted of crushing, screening, scrubbing to remove a contaminant coating, heavy-media separation of the coarser fractions, and jigging to upgrade the fines. Seven major products were prepared:

Product	Percent						
	Mn	Fe	SiO_2	Al_2O_3	P	K_2O	BaO
Premium coarse (chemical-grade)	52.5	2.0	2.9	2.9	0.090	1.00	3.00
Metallurgical lump	48.8	3.3	5.8	3.5	.090	2.50	.50
Siliceous lump	43.0	4.5	13.0	3.6	.070	2.70	.35
High-grade intermediates	43.0	6.5	8.5	6.0	.075	2.00	.72
Low-grade intermediates	39.0	6.9	12.0	7.0	.075	2.00	.60
Premium-grade fines	53.0	2.0	3.0	3.0	.090	0.80	2.30
Low-grade fines	37.0	11.5	12.5	5.8	.080	1.45	.35

Sulfur analyses, all 0.007 or 0.008; CaO, 0.10 or less; and Na_2O, 0.20 or less. Groote Eylandt shipments in 1973 were approximately 1.5 million short tons, bringing total shipments since the commencement of operations to more than 5.5 million tons. Expansion plans, if consummated, will result in a capacity sufficient to provide for annual sales of 2.2 million short tons of ore in 1976, with possible later expansion to 3 million tons as market and other conditions permit.[5] Strikes closed the mine during almost all of November.

Broken Hill Proprietary Co. Ltd., parent company of both Groote Eylandt Mining Co. Ltd. and Tasmanian Electro Metallurgical Co. Pty. Ltd. (TEMCO), announced that planned expansion of the latter's Bell Bay, Tasmania, plant would include a 24-megavolt-ampere furnace for production of ferromanganese or silicomanganese, a machine for sintering manganese ore, and the necessary modifications to power facilities, all of which were scheduled to be completed by the end of 1975. Groote Eylandt was to supply manganese ore; coke and coal were to come from Australia's eastern States; and regular tonnages of wood chips were to come from local sources. Bell Bay currently uses two electric furnaces to produce ferromanganese and silicomanganese: one rated at 13 megavolt-amperes, the other at 16 megavolt-amperes.[6]

Bolivia.—Exports of manganese ore, in terms of manganese content, were 170 short tons in 1974, 213 tons in 1973, and 30 tons in 1972. Exports for 1972 were reportedly by Grupo Minero Aral; those of 1973 and 1974 were identified only as "medium mines." Argentina was the recipient in 1974 and presumably was in 1973 and 1972, also.

The manganese ore bed at Mutún Mountain reportedly was undeveloped. Although feasibility studies for Mutún will be concerned primarily with development of its iron ores and its projected iron and steel complex, one study is planned to include exploration of the manganese horizon halfway up this mountain at its northernmost point where reserves have been estimated to amount to 500,000 tons of unstated grade. All activity at Mutún is by Empresa Siderúrgica Boliviana S.A. (SIDERSA), the Government's iron and steel enterprise.

Botswana.—The manganese ore produced in 1973 was unbeneficiated ore exported to the Republic of South Africa for treatment.

Brazil.—Amapá manganese ore shipments in 1973 by Indústria e Comércio de Minerios, S.A. (ICOMI) totaled 1,400,000 short tons, compared with 1,219,000 tons in 1972. The 1973 shipments were loaded out of the port of Santana in 68 vessel cargoes, with those for export going to 15 countries besides the United States: Argentina, Belgium, Czechoslovakia, Canada, England, France, Germany, Greece, the Netherlands, Italy, Japan, Mexico, Norway, Spain, and Yugoslavia.[7] The only Brazilian customer in 1974 was the ferromanganese producer, Eletrosiderurgica Brasileira, S.A. (SIBRA), in Bahia State, with deliveries made by coastal steamer at a freight rate of approximately $30 per ton, compared with a rate to the U.S. east coast of approximately $7 per ton. Total Brazilian consumption of manganese ore was estimated to be approximately 300,000 to 400,000 tons per year, most of which was trucked or railed to the consumer from mines in Minas Gerais and Goiás. The Urucum mine in Mato Grosso, in which United States Steel Corp. formerly had a large interest, ceased operations in 1972.[8] In 1973, production of manganese ore by the Meridional mine in Minas Gerais was 93,000 short tons having a manganese content of 37.4%; partial additional output from other mines in the State, as reported by the Central Railroad, was 39,000 tons. Three firms contributed to Brazil's production of 80,000 tons of high-carbon ferromanganese in 1974. SIBRA with 38,000 tons was the principal producer. One firm, Prometal Produtos Mètalurgicos, S.A. (PROMETAL), produced 4,900 tons of medium- and low-carbon ferromanganese; four firms produced 38,000 tons of silicomanganese.

Bulgaria.—Preliminary designs have been completed for developing the Dobrudzha manganese deposits, which have been under study for more than 4 years. An agreement was reported to have been reached between the Government and Kaiser Industries for cooperation in the development of manganese mining.[9]

Canada.—Metallurgical-grade manganese ore was consumed in 1973 to produce manganese ferroalloys by Chromium Mining & Smelting Corp., Ltd., Beauharnois, Quebec, and by Union Carbide Canada Limited, Beauharnois, Quebec. In addition, approximately 2,000 tons of battery-grade ore was used by producers of dry cells. Preliminary data show imports of manganese ore, in terms of manganese content, to have totaled 146,000 short tons in 1973, compared with 98,000 tons in 1972. The sources were as follows (1972 figures in parentheses): The United States, 48,000 tons (7,000); Gabon, 39,000 (30,000); Brazil, 26,000 (33,000); Zaire, 16,000 (14,000); the Republic of South Africa, 13,000 (zero); the U.S.S.R., 4,000 (3,000); Mexico, 415 (113); other, 3 (10,000). Ferromanganese imports totaled 27,000 tons, gross weight, in 1973, compared with 19,000 tons in 1972, distributed as follows: The United States, 12,000 tons (3,000); France, 6,000 (3,000); Norway, 5,000 (zero); the Republic of South Africa, 4,000 (12,000); Japan, 70 (47); other, zero (274). Silicomanganese imports were 11,000 tons, gross weight, in 1973 and 17,000 in 1972, with the following sources: The United States, 7,000 (8,000); Norway, 1,000 (7,000); the Republic of South Africa, 1,000 (zero); Yugoslavia, 1,000 (356); the Republic of Korea, zero (907). Exports of ferromanganese were 3,000 tons, gross weight, in 1973 and 2,000 tons in 1972, with almost all going to the United States in both years.[10]

Chile.—The manganese ore produced in 1973 had an average manganese content of 41.6%.

China, People's Republic of.—Manganese ore production in China remains largely a little known activity. An excerpt from the Hunan Provincial Service, September 27, 1973, stated that 35 small mines were opened in the 4 years previous in Ningyuan County of Hunan Province with production of 358,000 tons.[11]

France.—Production of blast furnace ferromanganese and spiegeleisen in 1974 totaled 588,000 short tons.

Gabon.—Negotiations with the Japanese firm, Okura-Trading, for construction of a ferromanganese plant advanced to the point where a company was contemplated with Government participation of 10% in addition to that of Cie. Minière de l'Ogooúe (COMILOG) and United States, French, Swedish, Italian, and Japanese firms. The plant could possibly be in operation by 1980.[12] COMILOG exported 2,103,000 short tons of metallurgical-grade ore and 54,000 tons of battery/chemical-grade ore in 1973.[13] Shipments of manganese ore in 1974 were 2.3 million tons. Production of battery- and chemical-grade ore in 1974 was 77,000 tons. Early in the year, the Gabon Government announced that it was purchasing a 10% equity in COMILOG. Later, a contract was signed with a European consortium for construction of that part of the Transgabon Railroad that will run from the port of Owendo, near Libreville, to Franceville, with completion expected in 1980 at a cost of approximately $400 million. This should permit a material increase in production of manganese ore by COMILOG after that time. Equity of United States Steel Corp. in COMILOG, formerly 49%, has been reduced to 44%.

Greece.—Concentrates produced in 1974 had a manganese content of 49% to 50%. Exports of pyrolusite from Greece in 1973 totaled 8,300 short tons, of which 4,200 tons went to West Germany and 3,900 tons went to France. Tekkosha Co. Ltd. and Mitsubishi Corporation started construction in March of their previously reported joint venture synthetic (electrolytic) manganese dioxide plant in the Thessaloniki Industrial Zone.

Iran.—Manganese ore produced in 1973 had an average manganese content of 40% to 44%.

Italy.—Production of manganese ore in 1973 was from the Gambatese mine where exploration of recent years for new ore was reported to have been unsuccessful. Imports of manganese ore in 1973 totaled

[10] Boucher, M. A. Manganese—1973. Mineral Development Sector, Department of Energy, Mines and Resources, Ottawa, Canada. December 1974, 7 pp.

[11] Mining Annual Review—1974 (London). June 1974, p. 403.

[12] U.S. Joint Publications Research Service. Translations on Africa, No. 1566. JPRS64143. Feb. 21, 1975, p. 11.

[13] Mining Journal (London). V. 282, No. 7231, Mar. 22, 1974, p. 206.

311,000 short tons, most of which came from the Republic of South Africa (176,000 tons), Gabon (101,000 tons), and Brazil (19,000 tons). Imports in 1972 totaled 300,000 tons. The manganese ore produced in 1974, as in 1973, was reported to have an average manganese content of 27%.

Japan.—Imports of manganese ore[14] in 1974 were approximately 2 million short tons with more than one-third of the total coming from each of Australia and the Republic of South Africa, more than 10% from Gabon, and lesser quantities from the U.S.S.R., Romania, India, Thailand, Malaysia, China, New Hebrides, Mexico, and Brazil. With ferromanganese having the lowest power requirement of the ferroalloys Japan produces for export, 2,000 kilowatt-hours per metric ton, and with power costs having doubled in the year to more than 7 yen (2.4 cents) per kilowatt-hour, it was expected that ferroalloy exports in the 1975 fiscal year (beginning April 1) might well be limited almost entirely to ferromanganese with the low-carbon grade being in the best competitive position. Japan Metals and Chemicals obtained some of its power from its own geothermal plant at a cost of 2.5 yen (0.9 cents) per kilowatt-hour. Expansion planned should provide sufficient power to provide all of the company's requirements from this source within the next 10 years.[15] In 1974, production of ferromanganese was 688,000 short tons; that of silicomanganese was 494,000 tons; electrolytic manganese metal, 9,545 tons; synthetic manganese dioxide, 49,374 tons. The manganese ore produced in the year had an average manganese content of 26.8%.

The Ministry of International Trade and Industry (MITI) was planning an economic stockpile that would include manganese among its inventories in a quantity expected to be approximately 10% of annual consumption.

Morocco.—The manganese ore produced in 1974 was chemical-grade ore or concentrate with an average manganese dioxide content of 84%. Virtually all came from the Imini mine, which has proven reserves of 1.65 million short tons, plus another possible 0.5 to 1 million tons, in a 12-mile-long seam running due west of the Ouarzazate-Marrakech road. Exploration for other deposits was being conducted to the east of the road. This underground mine operated as a joint venture of the Moroccan state mining monopoly, Bureau de Recherches et de Participations Minières (BRPM), and the French firm, Soc. Anonyme Chérifienne d'Etudes Minières (SACEM). The United States was the largest customer for its output, with most of the remainder going to western Europe.

New Hebrides.—Manganese ore produced in 1973 had an average manganese content of 42%.

Pakistan.—The ore produced in 1973, and probably earlier recent years, contained less than 35% manganese.

South Africa, Republic of.—Production of the various grades of metallurgical ore in 1973 was as follows, in short tons: 30% to 40% manganese, 2,898,000; 40% to 45%, 272,000; 45% to 48%, 307,000; and over 48%, 1,031,000. Local sales were, respectively, 625,000, 14,000, 56,000, 206,000 tons. Of the chemical ore produced, 87,000 tons contained 35% to 65% manganese dioxide, and 9,000 tons contained 65% to 75% manganese dioxide. Local sales were 90,000 and 7,400 tons, respectively. Production of ferruginous manganese ores, containing 15% to 30% manganese and 20% to 35% iron, totaled 73,000 tons. Exports were 185,000 tons; there were no local sales. Total exports of metallurgical ore were 3,868,000 tons. Only 350 tons of chemical ore was exported. Delta Manganese (Pty) Ltd. was in commercial production of electrolytic manganese metal by the middle of the year at its new plant at Nelspruit, Transvaal, with initial output going to Europe and Canada. Expansion was underway at the ferromanganese plant of Ferroalloys Ltd., in Natal.

Thailand.—Battery-grade (75% manganese dioxide) production in 1974 was 9,800 short tons. In 1973 it totaled 12,500 tons, of which 5,000 tons came from Lamphun Province, and 2,200 tons from Phrae Province, both in the Northern Region; and 3,900 tons were from Loei Province in the Eastern Region. The remainder came from four other provinces in the Northern Region and two in the Central Region. Songkhla Province in the Southern Region and Rayong in the Central Region each produced 9,900 tons of metallurgical ore in that year; Lamphun, Chiang Mai, and Phetchabun provinces in the Northern Region produced 3,400, 1,700 and 1,200 tons, respectively. Lesser quantities came from one other province in each of the Southern, Central, and Northern regions. Domestic consumption of battery-grade ore in 1973 was 5,700 tons, and no metallurgical ore was consumed. Exports of battery-grade ore totaled 3,900 tons, of which 2,200 tons went to Taiwan, 1,500 tons to Hong Kong, and 160 tons to Japan. Exports of metallurgical ore were 1,200 tons, all of which went to Taiwan except for less than 100 tons, which went to Hong Kong. In the 9 previous years, Japan and Hong Kong took most of the battery-grade ore that was exported, whereas Japan and Taiwan took most of the metallurgical ore, with Japan getting by far the larger part.

---

[14] The term "manganese ore" as used in this particular instance may include some lower grade manganiferous ores.

[15] Saito, F. Japan Sees Drop in Ferroalloy Exports. Am. Metal Market, v. 82, No. 99, May 21, 1975, pp. 25-26.

Zaire.—In November 1973, Société Minière de Kisenge (SMK) was nationalized with management unchanged and production continuing to be marketed by Beceka-Manganese, former owner of most of the company's shares. Mining was from three open pits at Kisenge in the southern part of Shaba (formerly Katanga) Province. SMK in 1973 exported 298,000 short tons of manganese oxide ore containing 48% to 55% manganese and 11,000 tons of carbonate ore averaging 35% manganese. Mining of the carbonate ore started in May 1973.

TECHNOLOGY

The basic oxygen furnace (BOF) steelmaking process has encountered problems resulting from the use of hot metal having a low manganese content due to the use of low-manganese iron ore pellets. In an effort to alleviate these problems, the Bureau of Mines studied the effects on pellet production of additions of manganiferous iron ores and of various manganese compounds. Additions of either manganese dioxide or manganiferous iron ores generally improved compression strength of the pellets with a corresponding loss of reducibility. Indications were that little modification of existing techniques and processes would be required, and the advantages of lower induration temperatures could possibly pay for part of the manganese cost. The high-silica manganiferous ores from Minnesota's Cuyuna Range had the disadvantage of increasing the silica content of the pellets. The study concluded that the addition of manganese to iron pellets was feasible, but that some penalties in smelting could be expected.[16]

A study by a group of steel-company and other metallurgists defined the principal uses of manganese in steelmaking: (1) To reduce hot shortness by forming manganese sulfide instead of ferrous sulfide; (2) to prevent carbide precipitation at grain boundaries; (3) to increase strength by solid solution hardening; (4) to increase toughness at high strength levels and low temperatures; (5) to increase hardenability; and (6) as a substitute for part of the nickel in austenitic stainless steels.[17] Desulfurization of hot metal before it reaches the BOF is a growing practice in spite of the fact that the cost of using calcium carbide or magnesium for external desulfurization is 3 times the cost of using manganese and fluorspar. The use of external desulfurization might eventually reach 80% or more of production, with some companies probably attaining 100%. Substitution of zirconium, titanium, or rare-earth elements, all of limited availability and relatively high cost, can only be used for killed steels, and the resulting flat-rolled killed steels have the undesirable feature of being relatively soft. Manganese will continue to be required for production of rimmed, capped, and semikilled steels. Manganese has no satisfactory substitutes for its alloying effects and for inhibiting carbide formation at grain boundaries. The general consensus of all those participating in the 1-day workshop associated with the study was that, although not essential for countering the harmful effects of sulfur, steel cannot be made in quantity without manganese; there is in reality no substitute for it.

Experimental work at the University of Illinois, Urbana, Ill., demonstrated that sawdust impregnated with an active form of manganese dioxide had considerably better efficiency and capacity for adsorption of hydrogen sulfide than did all activated carbons with which it was compared. Granulated activated carbon has been the most commonly used solid filter material for removing hydrogen sulfide from the air. Manganese dioxide impregnated sawdust has the disadvantage that it will ignite if allowed to dry out completely with exposure to temperatures of more than 100° C. Its efficiency was at a maximum at a relative humidity of 80%, whereas both it and the activated carbons were inefficient at relative humidities of less than 20%.[18]

[17] National Materials Advisory Board, National Research Council-National Academy of Sciences–National Academy of Engineering. A Semi-Delphi Exercise on Fluorspar and Manganese in Steelmaking. NMAB–317, 1974, 58 pp.

Further pursuit of the previously reported Trans-Atlantic Geotraverse (TAG) project of the National Oceanic and Atmospheric Administration (NOAA), U.S. Department of Commerce, confirmed the existence of hydrothermal manganese oxide deposits on the east wall of the median rift valley of the Mid-Atlantic Ridge. The deposits, estimated to cover 40 square miles, were reported to be of higher manganese content than the average for seafloor nodules but very poor in iron, nickel, cobalt, and copper. They were estimated to have a much more rapid growth rate than the nodules, to be still in the process of accumulation, and to occur where plate tectonic theory would expect them to be. Two volcanic peaks on the valley floor showed evidence of recent eruption. It is hoped to explore the deposit by drilling.[19]

Continuing, but as yet uncompleted, studies under the auspices of NOAA of the possible environmental effects of deep sea mining of manganese nodules have suggested that neither the beneficial nor the harmful effects of mining and lifting to surface will be significant. It has been contended that redistribution of sediments by turbidity currents and other natural phenomena are greater "by many orders of magnitude on a world-wide scale." However, the processing and extractive metallurgy of manganese nodules at sea, and the discharge of resulting waste materials, could be matters for serious concern unless adequate precautions are taken. It was noted that, at least for first-generation plants, economies would appear to dictate that the nodules be processed at an onshore facility.[20] An independent South African report, in addition to assessing all other aspects of the recovery possibilities for the ocean-floor manganese nodules, supported the foregoing discussion of environmental effects.[21]

Mercury

By V. Anthony Cammarota, Jr.[1]

Primary mercury production of 2,189 flasks,[2] valued at $616,619, was from 12 mines in California, Nevada, Alaska, and New York in 1974. During the year, only about six mines could be classified as consistent producers.

New Idria Mining & Chemical Co. put the town of Idria and the New Idria mercury mine in San Benito County, Calif., on the auction block, but there were no buyers. About 150 families had moved out in late 1973. In Nevada, Placer Amex Inc. announced plans to open the McDermitt mine, a 20,000-flask-per-year facility, at a cost of $9.7 million.

Secondary production of 8,293 flasks was down from the 1973 level. This includes 2,353 flasks sold by the General Services Administration (GSA).

The consumption of 59,479 flasks was 10% higher than that of 1973, although in the second half of 1974 consumption declined. The largest increases were noted for catalysts and electrolytic preparation of chlorine and caustic soda, with agriculture showing the largest decline.

General imports of 52,102 flasks were 13% higher than those of 1973; the United States continued to rely on foreign sources for almost all of its primary mercury demand. The major suppliers were Canada, Mexico, and Algeria. The U.S. rate of duty on primary mercury remained at $9.50 per flask. Exports were 466 flasks.

World production of mercury was 262,286 flasks, a 2% drop from that of 1973. Most countries produced mercury near 1973 levels. In Italy, the Government took over control of the mercury mines which had been showing losses over the past several years, and Japan's only mercury mine closed.

Representatives from Algeria, Italy, Mexico, Spain, Turkey, and Yugoslavia agreed to establish a floor price of $350 per flask. Following the meeting, New York prices advanced to the floor price, a gain of almost 20% within 6 weeks. By yearend, prices had retreated to the $150 level. The average New York price for the year was $281.69 per flask.

The Environmental Protection Agency (EPA) promulgated final effluent limitations for mercury-cell chlor-alkali plants and began public hearings on the use of mercury biocides.

Legislation and Government Programs.—Government financial assistance on a participatory basis was available for mercury exploration projects through the Office of Minerals Exploration, U.S. Geological Survey, to the extent of 75% of the acceptable costs. No contracts were executed during 1974.

GSA continued its sale of surplus mercury on a sealed-bid basis at the rate of 500 flasks per month. Sales totaled 2,353 flasks, with prices ranging from $277 per flask in February to $323 per flask in June. At yearend 2,275 flasks remained available for disposal.

No action was taken by Congress on authorizing the release of the total surplus of 157,405 flasks of mercury from the strategic stockpile. As of December 31, 1974, total strategic stockpile accumulations from all programs stood at 200,062 flasks.

Final effluent limitation guidelines for existing and new sources in the inorganic chemicals manufacturing category were promulgated by EPA. For mercury-cell plants, the daily effluent limitation is 0.00028 pound of mercury per 1,000 pounds of product for existing sources, and 0.00014 pound of mercury per 1,000 pounds of product for new sources.[3] EPA proposed an amendment to the emission standards for hazardous air pollutants which would limit mercury emissions from the incineration and drying of waste water treatment plant sludges to a maximum of 3,200 grams per day.[4] In addition, the National Institute for Occupational Safety and Health submitted criteria for a recommended limit of 0.05 milligram of mercury per cubic meter on the occupational exposure to inorganic mercury.[5]

---

[1] Physical scientist, Division of Nonferrous Metals.

[2] Flask as used throughout this chapter refers to the 76-pound flask.

The Commissioner of Food and Drugs proposed to establish an action level for mercury in fish and shellfish of 0.5 part per million.[6] This level gave a tenfold margin of safety to the vast majority of the U.S. population.

EPA opened hearings in October on the cancellation of biocidal uses of mercury, including mildewcides in paint. The hearings were recessed until February 1975 when witnesses for the registrants were scheduled to appear.

r Revised.

DOMESTIC PRODUCTION

Production of 2,189 flasks came from 12 mines in 1974, down from 24 in 1973. Many of the very small operations closed in 1974. A significant portion of the production, as byproduct mercury, came from a zinc smelter. Some exploration and development work was conducted by several small operations. Of the total production, 91% came from producers of over 100 flasks. Principal mines (properties producing 100 to 499 flasks) in 1974 were as follows:

State	County	Mine
Alaska	Kuskokwim River Region.	White Mountain.
California	Marin	Chileno Valley.
Do	Napa	Manhatten-One Shot.
Do	do	Oat Hill.
Do	Santa Clara	Guadalupe.
Do	do	New Almaden.
Nevada	Pershing	Red Bird.

California provided 60% of the total mercury production, up from 55% in 1973. The Red Bird mine was responsible for most of Nevada's production. In addition, the Carlin Gold Mining Co. continued to recover mercury as a byproduct at its gold mine in Eureka County. The White Mountain mine in Alaska shipped most of its cinnabar concentrate to Oregon for retorting, but exported the equivalent of about 54 flasks to the Orient.

Placer Amex Inc. began construction of a new flotation concentrator, and a furnace and condenser system at its open pit mine near the site of the old Cordero mine in Humboldt County, Nev. Reserves were estimated at 3 million tons of ore averaging 10 pounds of mercury per ton, about 15% to 25% of which is in the chloride mineral corderoite. The mill was designed to process about 100 tons of ore per day to produce a 60% concentrate feed for a Herreshoff furnace. The offgases were to be scrubbed and refrigerated to remove mercury and meet EPA mercury emission standards. Startup was expected in May 1975.

[6] Federal Register. Action Level for Mercury in Fish and Shellfish. V. 39, No. 236, Dec. 6, 1974, pp. 42738–42740.

The average grade of all ore processed in 1974, including ore treated in concentrators, decreased to 4.4 pounds of mercury per ton. Because of the insufficiency of reported data in 1974, the amount of ore treated and ore grade were based to a large extent on knowledge of producing areas and their historical data.

Secondary production of mercury fell to 8,293 flasks, from 10,329 flasks in 1973. Most of the decline represented inventory depletion of secondary mercury from a mercury-cell plant closed several years ago. Dental amalgams, scrap batteries, various types of sludges, mercury from a dismantled chlor-alkali plant, and discarded mercury-containing instruments were the major sources of secondary mercury.

Table 2.—Mercury produced in the United States, by State

1973	7,746	2,583	10,329
1974	5,940	2,353	8,293

CONSUMPTION AND USES

Consumption continued to climb for the third consecutive year, to 59,479 flasks. The largest gains were noted for catalysts (93%) and electrolytic preparation of chlorine and caustic soda (29%). Mercury compounds as catalysts found increased use in polyurethane formation, in which the mercury catalyst is mixed with the formulation and becomes part of the urethane structure. Agricultural use declined 46%, reflecting EPA's ban on many agricultural and industrial mercury biocides. The use of mercury in antifouling paint was not evident after the first quarter of 1974. The major uses for mercury were electrical apparatus, 33%; electrolytic preparation of chlorine and caustic soda, 28%; mildew-proofing paint, 11%; and industrial and control instruments, 10%.

Chlorine production increased by 6% to an estimated 10.9 million short tons, but only 24.8% of the total was produced in mercury cells, up slightly from 24.6% in 1973. Consumption of mercury per ton of chlorine produced increased to 0.48 pound, from 0.39 pound in 1973. The increase came about because the changeover in some plants from graphite to dimensionally stable anodes required a higher operating level of mercury in the cells.

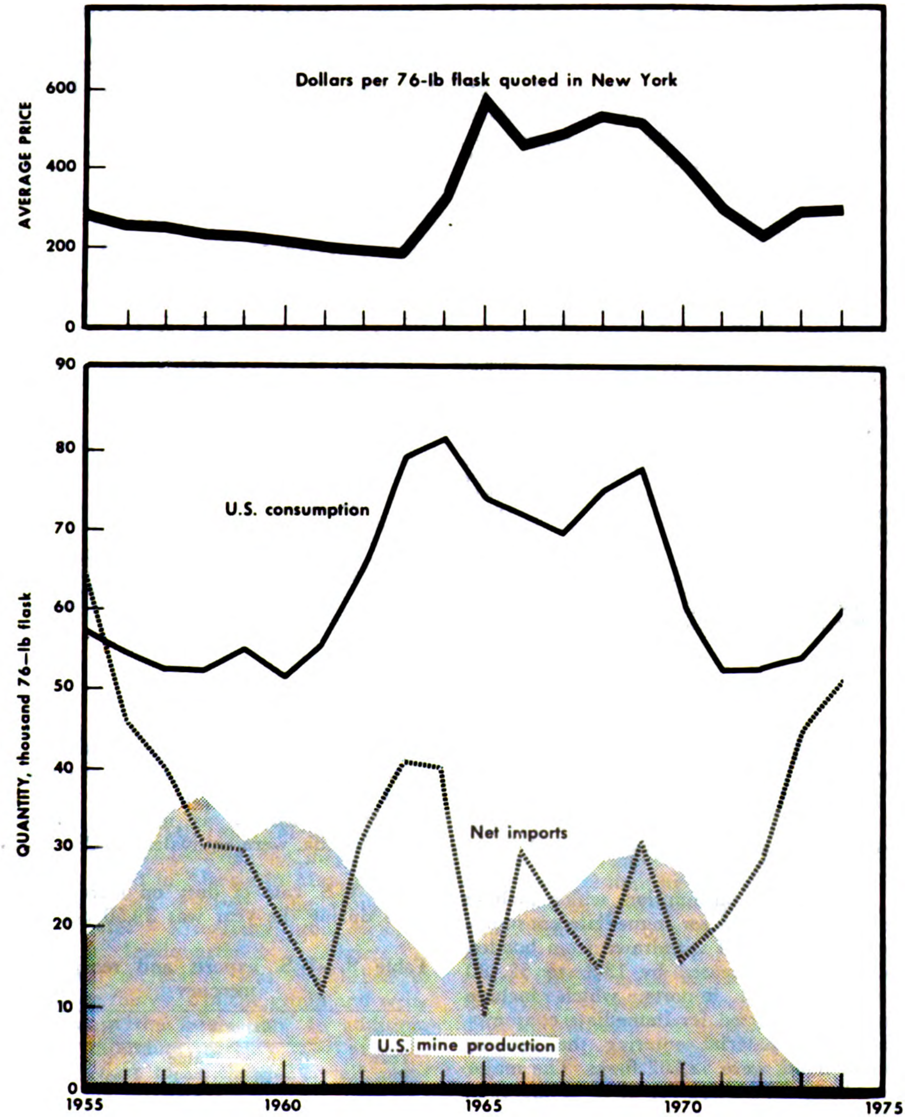

Figure 1.—Trends in production, consumption, and price of mercury.

PRICES

Mercury prices exhibited their characteristic volatility during the year. New York prices were stable in the $270 to $295 per flask range for the first 5 months of the year. After the May meeting of mercury producers in Algeria, at which a floor price of $350 per flask was set, the price climbed to that level within several weeks.

From July through December prices fell almost continuously, finishing the year at $190 to $225 per flask. Reasons cited for the precipitous drop in prices were the influx of substantial amounts of mercury from the U.S.S.R., People's Republic of China, and Turkey, traders selling surplus metal at a loss, low demand, some producers selling below the floor price, and the imminent opening of the McDermitt mine in Nevada. The average New York price was $281.69 per flask in 1974.

London prices followed the New York pattern, although usually they were lower by about $15 to $30 per flask. By late December the price had fallen to $150 to $175 per flask.

Table 8.—Average monthly prices of mercury at New York and London
(Per flask)

Month	1973		1974	
	New York [1]	London [2]	New York [1]	London [2]
January	$282.50	$260.72	$275.45	$266.72
February	304.78	289.38	284.22	269.50
March	314.36	303.94	288.27	270.25

FOREIGN TRADE

Mercury exports increased to 466 flasks from 342 flasks in 1973. The major recipients were Canada, the Republic of Korea, and Venezuela. In addition, cinnabar concentrate containing about 54 flasks was exported.

Imports for consumption, which include mercury imported for immediate consumption plus material withdrawn from bonded warehouses, increased by 13% to 52,180 flasks. General imports, which include mercury imported for immediate consumption plus material entering the country under bond, were 52,102 flasks. The major suppliers, accounting for 85% of the total imports, were Canada (33%), Mexico (20%), Algeria (20%), and Spain (12%). Included in the import figures are 506 flasks entering the country as secondary metal from Canada, Mexico, and the United Kingdom. Imports of mercury compounds, mainly as mercury cyanide from Canada, were equivalent to 286 flasks of metal.

The U.S. rate of duty on mercury imports during the year was $9.50 per flask.

WORLD REVIEW

World mercury production decreased to 262,286 flasks from 268,265 flasks in 1973. Italy, Mexico, Spain, and Yugoslavia accounted for 47% of the total. Representatives of Algeria, Italy, Mexico, Spain, Turkey, and Yugoslavia, the major world producers, met in Algeria in May. Canada attended as an observer. The group decided to create a mercury producer's organization, headquartered in Algiers. A provisional secretariat was established to coordinate the work of the group and write the rules of the association. In addition, it set a minimum mercury sales price of $350 per flask to be charged by all members of the group.

The Organization for Economic Cooperation and Development (OECD), whose 24 member countries include most of the industrialized market-economy nations of the world, including the United States, recommended that more attention be paid to limiting mercury emissions from mining and mineral-refining operations and coal burning, and also that mercury toxicity in humans be investigated. OECD asked its member countries to supply it with national consumption data and amounts of mercury discharged from chlor-alkali plants.

[e] Estimate. [p] Preliminary. [r] Revised.
[1] Exports.

The First International Mercury Congress was held in Barcelona, Spain, in May.[7] The meeting focused on geology and extractive metallurgy although biological effects of mercury received much attention. World cumulative demand for mercury was forecast at 10.5 million flasks based on a growth rate of 2.2% from 1974 to 2000. World reserves were considered sufficient to meet the demand. The level of world consumption in 1973 was given at about 245,000 flasks. Byproduct mercury from base metal refining was discussed as an increasingly important source of supply.

Canada.—Cominco, Ltd., produced 14,000 flasks, 12% more than in 1973. Ore production at its Pinchi Lake mine amounted to 173,000 tons, compared with 163,000 tons in 1973. Assuming that all the ore mined was treated to produce metal, the ore grade increased from 5.8 pounds of mercury per ton in 1973 to 6.2 pounds in 1974. Ore reserves at yearend were reported by Cominco to be 1,300,000 tons containing 110,000 flasks of mercury. The company reported that it has experienced no health problems at Pinchi Lake in the 6 years of operation.

Italy.—Italy's nonferrous metals agency, Ente Gestione Aziende Minerali Metallurgiche, (EGAM) acquired Monte Amiata Societa Minerario per Azioni and Stabilimento Minerario del Siele early in the year. An EGAM subsidiary will be responsible for the mercury operations through a new company, Societa Mercurifera Monte Amiata. In recent years the depletion of higher grade ore and high labor costs have made Italian mercury increasingly uncompetitive on the world market.

Metal production in 1974 was 24,950 flasks, a 24% decline from that of 1973, from ore that averaged 8.4 pounds of mercury per ton. Most of the production came from the Abbadia San Salvatore mine, with lesser quantities from the Solforate, Morone (Selvena), Bagnore, and Monte Labbro mines. About 1,000 workers were employed at the mines.

The Bagnore and Monte Labbro mines were shut down during the year and a modernization program was begun at the Solforate mine. By yearend work stopped in the remaining mines for about 1 month because of the large stock of metal, reportedly about 100,000 flasks.

Japan.—In late 1974 Japan's last mercury mine at Hokkaido was closed by Hokushin Mining Co. Consumption of mercury was reported to have declined drastically, especially in the chlor-alkali industry. About half of Japan's imports for the year came from Algeria.

TECHNOLOGY

A new mineral, corderoite ($Hg_3S_2Cl_2$), from the Cordero mine in Humboldt County, Nev., was found in samples of mercury ore from the playa sediments.[8] The occurrence of corderoite in the deposit suggests that it is of low-temperature and/or supergene origin.

Techniques for removing mercury from effluent streams continued to be the main emphasis for research. Polyethylenimine-modified wool was found to have a great ability to adsorb mercury from aqueous solution.[9] Sorption from liquids passing through a column was rapid and effective at the 1-part-per-million level. The mercury was readily desorbed, and the wool could be used repeatedly.

Molecular sieves have been adapted to removing mercury from gaseous effluents.[10] In a typical chlorine plant application, the hydrogen gas is compressed and cooled to condense most of the mercury, after which the gas passes through the adsorber. The adsorbed mercury is released from the column by a blast of hot gas and returned to the plant for reuse.

Georgia-Pacific Corp., supported by a grant from EPA, completed tests on a new process for recovering up to 99% of the mercury formerly considered unrecoverable in the waste water and process sludge from the chlorine plant.[11]

Mica

By Stanley Haines[1]

Domestic production of mica[2] consisted of a small quantity of sheet mica from two States, and a larger quantity of scrap, flake, and ground mica. Production of scrap, flake, and ground mica declined significantly from 1973 levels.

Consumption of block and film mica, largely imported, decreased in both quantity and value in 1974, after a small upturn between 1972 and 1973. Consumption of mica splittings increased for the third consecutive year to the highest level since 1967. Exports of all classes of mica increased in both quantity and value. Imports of uncut sheet and punch mica were at the lowest levels since 1938. Scrap and manufactured mica imports increased in both quantity and value.

Legislation and Government Programs.—The Defense Materials Inventory stockpile objectives for all categories of sheet mica remained the same. The General Services Administration continued to dispose of sheet mica. Table 2 summarizes the Defense Materials Inventory for mica as of December 31, 1974.

Phlogopite splittings	200,000	3,701,510	32,851,128

[1] Total inventory includes nonstockpile-grade materials: Muscovite block, stained or better, 878,704 pounds; muscovite film, first and second qualities, 640 pounds; and phlogopite block, 100,116 pounds.
[2] Includes 34,282 pounds nonstockpile-grade material.

DOMESTIC PRODUCTION

Sheet Mica.—A small quantity of sheet mica was produced in Connecticut and North Carolina. The sheet mica produced was generally of low quality and was derived from occasional pockets uncovered by quarry blasting at pegmatite feldspar operations. No mica was mined as the primary product of the producing company.

Scrap and Flake Mica.—Production of scrap and flake mica declined 11% from 1973, to 136,966 tons in 1974. The value of production declined 10%, from $6,081,893 in 1973 to $5,474,636 in 1974. North Carolina remained the leading scrap and flake mica producing State, with almost 56% of total production. The remaining output of scrap and flake mica came from Alabama, Arizona, Connecticut, Georgia, New Mexico, South Dakota, and South Carolina. Flake mica continued to be produced primarily from the beneficiation of pegmatite ores and clay deposits.

Ground Mica.—Sales of ground mica decreased 14% from the revised 1973 quantity of 136,501 tons to 117,363 tons in 1974. Total value of sales increased 7% over 1973, to $10,171,000 in 1974. Sixteen companies, operating a total of 18 plants, processed scrap and flake mica. Twelve of these plants produced dry-ground mica, four produced wet-ground mica, and two produced both wet- and dry-ground mica.

[r] Revised.

[1] Domestic and some imported scrap.

[2] Data may not add to total shown because of independent rounding.

CONSUMPTION AND USES

Sheet Mica.—Fabrication of block and film mica declined 23% from 1973, to 973,928 pounds in 1974. Of the total consumption, 93% was muscovite block, 6% was phlogopite (magnesium mica) block, and 1% was muscovite film.

Vacuum tubes required 64% of the total muscovite block fabricated. The remaining fabricated muscovite block was used in gage glass and diaphragms 3%, capacitors 1%, and other uses 32%. Lower than Stained quality muscovite block mica was in greatest demand and accounted for almost 66% of consumption; Stained, 33%; and Good Stained or better, 1%.

Muscovite film consumption declined 15%, from 10,148 pounds in 1973 to 8,671 pounds in 1974. The film was primarily consumed in the fabrication of capacitors.

Muscovite block and film were consumed by 13 companies in 7 States. In 1974, New Jersey with four consuming plants, New York with three, North Carolina with two, and Pennsylvania with one consumed 75% of the total domestically fabricated block and film. Phlogopite block consumption dropped from 69,899 pounds in 1973 to 62,513 pounds in 1974. Phlogopite was consumed by six companies in five States. Virginia and New Jersey were the primary fabricating States.

Consumption of mica splittings, both muscovite and phlogopite, increased for the third consecutive year, from 5,178,000 pounds in 1973 to 6,186,000 pounds in 1974. India and the Malagasy Republic supplied the bulk of the splittings consumed domestically. Splittings were fabricated into various built-up mica products by 11 companies with 12 plants in 8 States. Six companies with six plants located in New Hampshire, New York, and Ohio consumed 4.9 million pounds of splittings, or 80% of total consumption.

Built-up-Mica.—This mica-based substitute was produced in various forms, primarily for use as electrical insulating material. Production of all major built-up mica products increased in quantity and value. The forms of built-up mica in greatest demand were segment plate 29%, molding plate 25%, and tape 24%.

Reconstructed Mica.—Three companies continued to manufacture this mica-based alternate material from good-quality delaminated scrap mica. The manufacturing companies were General Electric Co. at Schenectady, N.Y.; Samica Corp. at Rutland, Vt.; and Acim Paper Corp. at New Hyde Park, N.Y. There were no published data available relating to the quantity and value of the reconstituted mica produced during the year.

Ground Mica.—Ground mica for use in construction-related industries declined significantly. Sales of ground mica used for roofing materials, paint, and joint cement declined 55%, 10%, and 20%, respectively.

[1] Includes mica used for molded electric insulation, annealing, well drilling, textile and decorative coating, texture paint, and uses indicated by symbol W.

[2] Data may not add to total shown because of independent rounding.

STOCKS

At yearend there was about 3.9 million pounds of sheet mica in fabricators' stocks. Of this total 84% was splittings, 15.5% was block, and 0.5% was film. This information was obtained by direct canvass of sheet mica fabricators. Similar information is not available for scrap, flake and ground mica. It is estimated that producers maintain inventories of ground mica equal to 5% to 10% of production.

PRICES

The average value of imported muscovite sheet in 1974, based on consumption data, follows: Block, $2.04 per pound; film, $4.36 per pound; and splittings, $0.44 per pound. The average value of phlogopite sheet mica, also based on consumption data, follows: Phlogopite block, $2.13 per pound; and phlogopite splittings, $0.80 per pound.

The average value of scrap and flake mica produced during 1974 was $39.96 per ton. Prices for wet-ground mica quoted in the Chemical Marketing Reporter showed significant increases from 1973. Dry-ground prices remained about the same as 1973. Yearend prices are shown in table 10.

Table 10.—Price of dry- or wet-ground mica in the United States in 1974 [1]

	Cents per pound
Dry-ground:	
Joint cement, 100 mesh	4–5
Plastic, 100 mesh	4–5
Roofing, 20 to 80 mesh	2–3½
Wet-ground: [2]	
Paint or lacquer, 325 mesh	11–13
Rubber	11–13
Wall paper	12–18

[1] In bags at works, carlots, unless otherwise noted.

[2] Freight allowed east of the Mississippi River.

FOREIGN TRADE

Total mica exports, as summarized in table 11, increased 14% in quantity and 24% in value over the 1973 figures. Over 50% of the sheet, scrap, flake, and ground mica exported was shipped to Canada, Singapore, and France. Reported export data did not provide information on the grade or type of mica exported, but it is assumed that the major portion of the material exported was ground mica.

Imports of scrap and waste mica increased 31% over those of 1973. Imports of sheet mica decreased 32% in quantity and 25% in value below 1973 levels. Processed mica imports increased 37% in quantity and 14% in value. There have been no imports of phlogopite waste and scrap since 1972.

WORLD REVIEW

World production of all forms of mica declined more than 4% from 1973 to 1974. India remained the world leader for production of sheet mica. The United States continued as the major world producer of scrap and flake mica.

India.—The Mica Trading Corp. (MITCO) was established as a subsidiary of the Minerals and Metals Trading Corp. (MMTC) to handle marketing of mica. The floor price for mica was increased 40% in February, with another rise expected in January 1975.

Exports of all forms of mica increased in 1974. It was estimated that almost 60% of the exports were taken by East Germany, Czechoslovakia, Hungary, Romania, the U.S.S.R., and Bulgaria.[3]

Malagasy Republic.—Malagasy remained the major world source of phlogopite mica with production of almost 1.9 million pounds of block, splittings, and scrap during the year. Over 64% of production consisted of splittings; the remainder was block and scrap.

TECHNOLOGY

A combination of synthetic mica and special glass has resulted in a new high-temperature electrical insulating material. This material, developed as a substitute for fired circuits, not only can withstand temperatures as high as 1,100° F, but it is also arc resistant, nontracking, noncombustible, and lightweight.[4]

The Wet-Ground Mica Association reported two experimental new uses of wet-ground mica. The first use involves wet-ground mica spread around crops to help control aphid infestation instead of the previously used aluminum foil. The other new development involves mica used as a shading compound on greenhouses. The ground mica is deposited on greenhouses during periods of intense sunlight that may damage the plants inside. The mica allows enough light for plant growth, but will lower the intensity below harmful levels. The mica is easily removed when no longer needed.

Molybdenum

By Andrew Kuklis [1]

World molybdenum consumption rose to an estimated 200 million pounds, apparently due to increased use of high-strength, low-alloy steel in energy related applications, principally the manufacture of large-diameter line pipe for hydrocarbons transmission. For the second consecutive year, consumption exceeded production. Molybdenum output as a byproduct was considerably lower in 1974 because of a drop in demand for copper, the primary associated mineral. World industrial and domestic government stocks were reduced significantly. Molybdenum production facilities were being expanded in many parts of the world.

[r] Revised.

Legislation and Government Programs.—The General Services Administration (GSA) disposed of over 35 million pounds of molybdenum from the Government's stockpile. Most was sold to domestic producers under long-term, buy-back agreements negotiated during the year. At yearend, molybdenum in the national stockpile totaled 2.1 million pounds. The material was expected to be available for sale periodically on a sealed-bid basis to producers, processors, and consumers. GSA stockpiles contained an additional 3.7 million pounds of molybdenum material that was classed as sold, but was unshipped.

Table 2.—U.S. Government molybdenum stockpile material inventories on Dec. 31, 1974

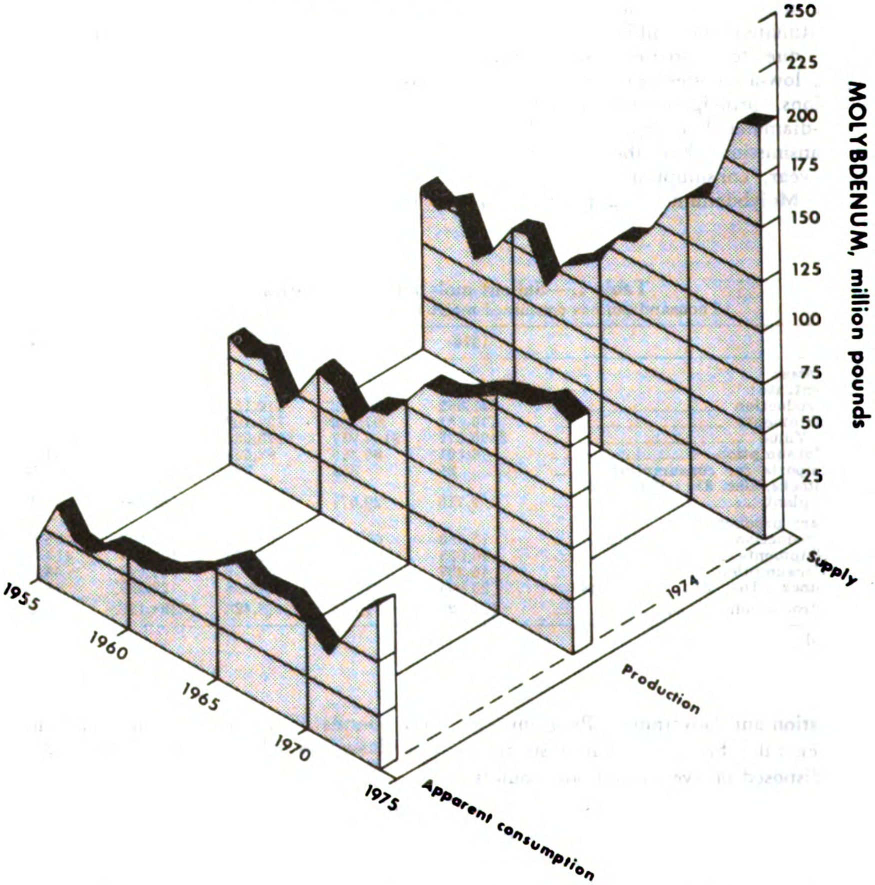

Figure 1.—Apparent consumption, production, and supply of molybdenum in the United States.

DOMESTIC PRODUCTION

Molybdenum output in concentrate declined nearly 4 million pounds from the 1973 record production year. Production from primary sources rose significantly but failed to offset lower output at byproduct plants. One byproduct plant reportedly did not recover molybdenum in 1974.

Ores processed at concentrators for molybdenum totaled over 192 million tons; the bulk consisting of byproduct ores. The concentrators recovered over 112 million pounds of molybdenum, 3% less than the quantity recovered in 1973. Of the total output in 1974, about 34% was as a byproduct from ores of copper, tungsten, and uranium, and the remaining 66% was recovered from ores processed for molybdenum.

Molybdenum output from primary ore rose nearly 11% compared with that of 1973. Three operations processed nearly 22 million tons of ore from which over 74 million pounds of molybdenum was recovered. The Urad mine was operated at reduced levels during the year and subsequently closed at yearend. Output at the Climax mine, the world's largest underground molybdenum operation, rose nearly 17% over that of 1973. The record production at Climax prevented a decline in output from primary sources.

Output of molybdenum at byproduct plants decreased over 11 million pounds compared with that of 1973. Lower production was due principally to a drop in demand for copper, an associated metal. Byproduct molybdenum from copper porphyry ores was recovered by 9 companies at 13 plants, 1 plant less than in 1973. The Inspiration facility of Inspiration Consolidated Copper Co. did not recover molybdenum in 1974. Of the 13 plants, only 2 increased their output, the remaining 11 plants had lower production compared with 1973 output. Lower production also was reported at uranium and tungsten byproduct operations.

The Sierrita mine of Duval Sierrita Corp. was the largest byproduct producer. The Utah mine of Kennecott Copper Corp. and the San Manuel mine of Magma Copper Co. ranked second and third, respectively. These three mines were responsible for about two-thirds of the byproduct molybdenum produced in the United States. Six companies, two primary and four byproduct producers, accounted for over 97% of the domestic output or 61% of the world output of molybdenum in 1974.

Demand for molybdenum remained strong during 1974 because of record consumption by the domestic steel industry and large exports to foreign markets. The molybdenum industry continued expanding production facilities to meet this demand, both in the mining and manufacturing sectors.

New labor contracts were negotiated in 1974 for most molybdenum industry employees. At midyear, some production was lost at byproduct plants because of a shutdown during prolonged contract negotiations. These labor agreements were expected to provide a climate for uninterrupted molybdenum production through 1977.

Molybdenum Corporation of America (Molycorp) reported a record output of 11.2 million pounds of molybdenum at its Questa open pit mine in New Mexico. A modified mining system was employed by the company to increase molybdenum production and to lower mining costs. Exploratory drilling was conducted during the year to increase ore reserves. The company completed 19 diamond drill holes in a new mineralized zone adjacent and to the southwest of the open pit mine. Twelve holes intersected a thick mineralized zone averaging 0.32% molybdenite. Exploratory drilling and other investigative work was continued into 1975. On completion of the program, a feasibility study was to be made to ascertain tonnage, grade, waste-to-ore ratio, and other operating parameters in preparation for expanding production at the property.

At midyear, construction was underway to build a molybdenum conversion plant on a 500-acre site near Ft. Madison, Iowa, by AMAX Specialty Metals Corp., a division of AMAX, Inc. The facility will produce 3.5 million pounds of ammonium molybdate and other derivative products for use in the chemical, metallurgical, and petroleum industries. It was expected to be the world's largest and most modern plant for manufacturing molybdate products; completion was scheduled for early in 1975.

The modernization program at AMAX's

Langeloth, Pa., roasting facility was continued. Most of the major equipment was to be replaced, and processes were to be automated. It was reported that over $10 million was authorized for pollution control and related equipment. Oxides of sulfur will be removed from the flue gases and converted to sulfuric acid by a contact process. Additional equipment will be installed to recover molybdenum contained in the flue gases. Expenditures for construction of the new Fort Madison plant and modernization of processing and roasting operations at Langeloth were estimated at over $50 million.

AMAX, Inc. continued both development and mining operations at its Climax open pit mine. Additional ore headings and haulage roads were prepared to increase production. At yearend, output of molybdenum ore reportedly rose to 7,000 tons per day. Underground mining operations were accelerated to increase ore production because of increased demand for molybdenum and anticipated closing of the Urad mine. Mining on the Phillipson level was discontinued due to exhaustion of ore reserves. Total molybdenum output for 1974 at the Climax property, open pit and underground, rose 8.5 million pounds compared with that of 1973.

The Urad molybdenum mine, operated by AMAX, Inc., was closed on November 29, 1974, because of exhaustion of ore reserves. The mine was developed at a cost of $30 million in 1967 to alleviate a shortage of molybdenum. Urad's ore supply was known to be limited to about 6 to 7 years of production. Employees were expected to be transferred to the nearby Henderson molybdenum mine currently under development. Urad's output of molybdenum totaled nearly 50 million pounds for the 1967 to 1974 period. At yearend, a comprehensive land reclamation program, costing $6 million, was underway at the mine site. The work will include landfill, reseeding, and closing of mine openings.

Development at the Henderson molybdenum mine near Empire, Colo., was continued. Projects underway included construction of an ore haulage tunnel, developing additional production headings in the ore body, and building a concentrator. At yearend, about 85% of the 10-mile-long tunnel was completed. Tunnel construction was conducted in two directions, from the mine by AMAX employees and from the concentrator by a contractor. AMAX employed 4 crews of 25 men each and worked 7 days per week in driving the tunnel. Dravo Corp., a mine development contractor, was driving the 15- by 16-foot tunnel from the concentrator to the mine. Steel arch sets on 4-foot centers were used for ground support. Drilling was conducted with a four-machine jumbo and the blasted rock was loaded by a belt-loader onto a train of cars for transportation to an outside muck pile. The two tunnels were expected to meet early in the second quarter of 1975. A considerable footage of headings have been completed in preparation for mining of the ore body.

Harrison Western Corp., an international mine development contractor, initiated construction of the No. 3 shaft at midyear at the Henderson mine. The 23-foot diameter shaft will be sunk to a depth of 2,300 feet and will be utilized for ventilation purposes.

Duval Corporation started construction of a ferromolybdenum production plant adjacent to the Sierrita and Esperanza mine, mill, and roaster complex near Sahuarita, Ariz. The facility will utilize an exothermic process in producing ferromolybdenum at a rate of 3.5 million pounds per year. Startup operations were scheduled for the second quarter of 1975.

Cyprus Bagdad Copper Co., formerly Bagdad Copper Corp., was expanding mining and milling operations at its Bagdad facility, 70 miles west of Prescott, Ariz. Fluor Utah, Inc., and Holmes & Narver, Inc., were engaged to provide design, procurement, and engineering services for the project. An automated concentrator, capable of processing 40,000 tons of copper-molybdenum ore, will contain primary crushing, autogenous grinding, standard flotation, concentrate handling, and molybdenum recovery sections. Ancillary facilities scheduled for construction include a tailings disposal and water recycling system, warehouse, mine and mill offices and shops, and an enlarged employees residential community. The project, costing an estimated $200 million, was expected to be completed late in 1977.

Cyprus Mines Corp. initiated a feasibility study on treating byproduct molybdenum concentrate by the Cymoly process. The Cymoly process was developed by Molycorp to produce pure molybdenum oxide from low-grade molybdenum concentrate. Pilot-plant tests have been conducted on concentrate by Cyprus Mines Corp.'s engineers at the Washington, Pa., plant of Molycorp.

Cyprus Mines Corp. continued surface and underground exploratory drilling to further delineate the mineralized zone at its Thompson Creek molybdenum prospect in central Idaho. A feasibility study was completed to determine the economic parameters of the property at mining rates of 20,000 tons and upward. A estimated $70 to $75 million would be required to develop Thompson Creek.

S.W. Shattuck Chemical Co. Inc., a subsidiary of Engelhard Minerals & Chemical Corp., planned to spend $500,000 for expanding its molybdenum and rhenium product manufacturing facilities. Included in the expansion was installation of a crystallizer which would double capacity for molybdate output. The company purchases byproduct molybdenum concentrate to produce ammonium and sodium molybdates, high-purity molybdic oxide, and rhenium compounds.

[1] Includes molybdic oxide, briquets, molybdic acid, and molybdenum oxide.
[2] Includes ferromolybdenum, calcium molybdate, phosphomolybdic acid, molybdenum disulfide, pellets, molybdenum pentachloride, and molybdenum hexacarbonyl.

CONSUMPTION AND USES

Domestic consumption of molybdenum in concentrate rose 11% compared with 1973 figures. Most of the concentrate, except that consumed in the production of purified molybdenum disulfide, was converted to molybdic oxide for direct use or to produce other molybdenum products. Output of purified molybdenum disulfide for lubricant purposes declined significantly compared with that of 1973.

Domestic end use consumption of molybdenum materials rose 6.4 million pounds in 1974 and was 11% higher than in 1973 (table 5). The increase in 1974 was the third consecutive consumption increase. It was due to higher output of steel, and specifically to increased use of high-strength, low-alloy steel for large-diameter line pipe. Molybdenum consumed in carbon, alloy, and stainless steels rose 35%, 13%, and 18%, respectively, compared with that of 1973. The percent increase in other steel-consuming sectors was in line with that of total consumption. Steel manufacturers take advantage of unique properties that molybdenum imparts to steel such as hardenability, corrosion resistance, strengthening, and toughness.

Development of new markets to increase consumption of molybdenum for chemical and metallurgical applications was continued. A new ferritic stainless steel containing 2% molybdenum was marketed for use in the manufacture of hotwater tanks, water tubes, heat exchangers, and other chemical processing equipment.

Researchers were investigating the use of special molybdenum steels in automobile engines designed for nonleaded fuels, for rock-drilling products, and higher strength steel pipe for use in drilling oil and gas wells to greater depths.

The Pesses Co., supplier of ferroalloys and specialty metal products, announced it was establishing a manufacturing operation at Solon, Ohio. Molybdenum ferroalloys would be among the company's principal products. The company has obtained molybdenum products from outside sources, but increased shipping costs led to the decision to manufacture its own molybdenum.

Battelle Memorial Institute installed a furnace muffle at its isostatic processing system laboratory in Columbus, Ohio. The structure, 4½ feet in diameter and 12½ feet in height, was the largest on record fabricated for commercial applications from a molybdenum alloy. It will be used in conjunction with a furnace operating at temperatures in excess of 2,400° F and at a pressure of 15,000 pound per square inch (psi).

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified."

[1] Includes calcium molybdate.

[2] Includes purified molybdenum disulfide, molybdenite concentrate added directly to steel, molybdenum metal powder, molybdenum metal pellets, and other molybdenum materials.

[3] Includes magnetic and nonferrous alloys.

STOCKS

The industrial inventory of molybdenum in concentrate and products totaled 41.6 million pounds, 21% less than at yearend 1973. Molybdenum in stocks at mines and plants dropped dramatically, those at producer plants decreased 28%, but those at consumer plants increased 49% compared with 1973 figures.

PRICES

The year 1974 was noted for sharply rising prices on all molybdenum products. The price stability that characterized molybdenum products during the past 5 years ended in February when producers increased prices an average of 10%. Subsequently, three additional price increases were instituted during the year. Higher operating costs due to inflation accounted for the rising molybdenum prices.

At yearend, price increases for molybdenum again were announced on domestic sales made on or after January 1, 1975. The following tabulation shows prices published in the January 6, 1975 issue of Metals Week for molybdenum and related products per pound of contained molybdenum:

Climax concentrate	$2.43
Byproduct concentrate	2.00–2.36
Climax oxide/cans	2.69
K-1 oxide/cans	2.69
K-2 oxide/cans	2.62
Ferromolybdenum/Climax lump	3.25
Ferromolybdenum/Climax powder	3.19

FOREIGN TRADE

Exports.—Exports of molybdenum in sulfide and oxide totaling 78.7 million pounds exceeded those shipped during the previous record year of 1973. Foreign markets received about 70% of the U.S. output compared with 64% in 1973. The Netherlands again was the principal destination, receiving 45% of the total. Most of the material entering the Netherlands was reshipped to other European countries, including those countries with controlled market economies. The new record high in exports was due to increased world demand and relatively low prices on foreign markets caused by the devalued and downward floating dollar.

Ferromolybdenum valued at $7.1 million was exported to 21 countries; Japan received 55% of the total value of shipments. Exports rose dramatically compared with 1973.

Other molybdenum products exported included metal and alloy in crude form, wire, powder, and semifabricated forms. Total value of these export products was nearly $6.9 million compared with $5.2 million in 1973. Metal and alloys (including scrap) totaling 104,935 pounds was shipped to 12 countries. The Republic of South Africa and West Germany received 59% of the exports. Molybdenum wire totaling 415,480 pounds was shipped to 34 countries. West Germany, Canada, France, Brazil, Israel, and Japan received 300,712 pounds, or over 72% of the total exported. Molybdenum powder exports of 202,785 pounds was shipped to 16 countries; Japan, the Netherlands, and Sweden received 86% of the total. Exports of semifabricated forms, n.e.c., totaled 251,088 pounds and were shipped to 24 countries. Five countries—the United Kingdom, Australia, West Germany, Canada, and the Netherlands—received nearly 73% of these exports.

[1] Ferromolybdenum contains about 60% to 65% molybdenum.
[2] Less than ½ unit.

Imports.—According to the U.S. Department of Commerce, molybdenum products imported during 1974 included concentrate, metal, and chemicals. Total value of these products was reported at $2.6 million. A small quantity of concentrate containing 144,124 pounds of molybdenum was imported from Mexico and Canada. Seven countries exported metal products containing 229,692 pounds of molybdenum to the United States. Canada and the Netherlands were the source of about 61% of the shipments. Molybdenum chemicals entering the United States included ammonium molybdate, inorganic compounds, other molybdenum compounds, and molybdenum orange pigment. Two countries, the Netherlands and West Germany, shipped ammonium molybdate containing 169,483 pounds of molybdenum to the United States. The Netherlands supplied most of the material. A small quantity of inorganic compounds containing 3,872 pounds of molybdenum came from Italy. Imports of other molybdenum compounds totaling 129,797 pounds came from five countries; Chile and the Netherlands supplied over 60% of the total imports. The United States imported molybdenum orange from three countries—Canada Japan, and Mexico.

Table 9.—U.S. import duties

Item	Articles	Rate of duty, Jan. 1, 1975 [1]
601.33	Molybdenum ore	12 cents per pound on molybdenum content.
603.40	Material in chief value molybdenum	10 cents per pound on molybdenum content plus 3% ad valorem.
607.40	Ferromolybdenum	10 cents per pound on molybdenum content plus 3% ad valorem.
	Molybdenum:	
628.70	Waste and scrap	10.5% ad valorem.[2]
628.72	Unwrought	10 cents per pound on molybdenum content plus 3% ad valorem.
628.74	Wrought	12.5% ad valorem.
	Molybdenum chemicals:	
417.28	Ammonium molybdate	10 cents per pound on molybdenum content plus 3% ad valorem.

[1] Not applicable to Communist countries.
[2] Duty on waste and scrap temporarily suspended.

WORLD REVIEW

World molybdenum production increased about 4.2 million pounds compared with that of 1973. About one-half of production was from byproduct sources, principally copper. Lower demand for copper due to depressed world economic conditions resulted in a decrease in output of byproduct molybdenum. Two countries, the United States and Canada, accounted for about 75% of molybdenum output. No official statistics are available on molybdenum production in Australia, Bulgaria, People's Republic of China, and the U.S.S.R., but estimates for these countries were included in the worlds total in table 10.

Table 10.—Molybdenum: World mine production by country
(Thousand pounds contained molybdenum)

Country [1]	1972	1973	1974 [p]
Australia	[r] 9	[e] [r] 2	[e] 25
Bulgaria [e]	310	310	310

United States	112,138	115,859	112,011
Total	[r] 178,423	184,122	188,274

[e] Estimate. [p] Preliminary. [r] Revised.
[1] In addition to the countries listed, Argentina, North Korea, Nigeria, Romania, Territory of South West Africa, and Spain also produce molybdenum, but information is inadequate to make reliable estimates of output levels.

Australia.—A rich, pipe-type mineralization containing principally molybdenum and other associated minerals was reportedly discovered near Rocky River, 35 miles south of Tenterfield, State of New South Wales. The prospect, located at a depth of 70 feet, was being drilled to determine the extent of mineralization.

Argentina.—Cia. Minera Aquilar S.A., subsidiary of St. Joe Mineral Corp., conducted additional exploratory drilling on the Pachou porphyry copper deposit which also contains molybdenum. Ore reserves were revised upward to 550 million tons from the 270 million tons reported in 1973. The grade of the ore was reported to average 0.65% copper and 0.015% molybdenite. Exploration of the deposit and metallurgical testing of the ore was continued to develop necessary data for a feasibility study of the deposit. Some high-grade copper mineralization exists near the surface, hence the deposit is amenable to open pit mining methods.

Canada.—Molybdenum production declined 788,000 pounds in 1974 and was 2.6% lower than in 1973. Reduced production at byproduct plants and labor problems at the Endako mine, the nations largest primary producer, was responsible for lower molybdenum output. Despite a drop in production, Canada remained in second place among producers of molybdenum and supplied 16% of world output.

Although Canadian consumption increased substantially over the past years, the industry remained dependent on export markets to maintain a viable molybdenum mining industry. Exports rose from 24.6 million to 27.4 million pounds in 1974, an increase of over 11% compared with those of 1973. Japan, Belgium, and Luxembourg received about 70% of the molybdenum shipments.

A strike was instituted at the Endako mine of Canex Placer Ltd. on October 11, 1974, by the Canadian Association of Industrial Mechanical and Allied Workers Union. Consequently, on October 17 the company declared a force majeure on deliveries of molybdenite concentrate, molybdic oxides, and ferromolybdenum. The workers returned to work in mid-December when the dispute was settled.

Exploration of potentially minable deposits of molybdenum continued in Canada, particularly in the Western Provinces. Improvement in world molybdenum demand resulted in reopening of a mine, and increasing throughput at concentrators processing primary ores.

Casino Silver Mines Ltd. reportedly drilled an ore deposit totaling 180 million tons having an average grade of 0.37% copper and 0.04% molybdenite. The Casino property, located nearly 200 miles northwest of Whitehorse, Yukon Territory, is amenable to open pit mining and has a waste-to-ore stripping ratio of 1.7 to 1. The ore also contained an undisclosed amount of gold and silver which can be economically recovered. Plans for development of the deposit were not announced.

Brynnor Mines Ltd., subsidiary of Noranda Mines Ltd., reopened the Boss Mountain mine because of an increasing demand for molybdenum. The mine had been shutdown since December 3, 1971. Mine production for its last year of operations amounted to 334,500 tons of molybdenite ore. At yearend, 1971, ore reserves were reported at 2.7 million tons averaging 0.4% molybdenite. A 1,000-ton-per-day concentrator was maintained in operating condition during the shutdown.

Western Mines Ltd. negotiated an agreement with Granite Mountain Mines Ltd. to prepare a feasibility study and conduct additional exploration drilling and testing on a copper-molybdenum deposit near Powell River in British Columbia. The deposit reportedly contains an estimated 90 million tons of ore having an average grade of 0.32% copper and 0.02% molybdenite.

The Granby Mining Co. Ltd. renewed its option on the Carmi molybdenum deposit near Kelowna, British Columbia, owned by Vestors Exploration Ltd. Drilling to date reportedly outlined molybdenum mineralization estimated at 29 million tons of ore having an average grade of 0.22% molybdenite. The company will drill an additional 25 holes and conduct other investigative work costing an estimated $1 million. The property comprises a block of 176 mineral claims. Previous drilling by the owner resulted in discovery of an impressive molybdenum deposit amenable to open pit mining.

Japan.—Mitsubishi International Corp. was designated as the exclusive sales agent in Japan for molybdenum and rare-earth mineral products manufactured by Molycorp. The agreement would be effective on January 1, 1975. In return for the sales agency, Mitsubishi International Corp. would purchase $5 million worth of subordinated notes convertible into Molycorp's common stock.

Mexico.—Lytton Minerals Ltd. acquired interest in the La Verde copper-molybdenum deposit in Michoacán State. Additional exploratory drilling, metallurgical testing of the ore, and a feasibility study was completed on the mineral deposit. A viable mining operation processing 16,500 tons of ore per day was ascertained by the study. Reserves were calculated totaling over 87 million tons of ore averaging 0.7% copper and 0.02% molybdenite.

Mexicana de Cobre S.A. obtained additional financing from a consortium of International banking institutions to develop the La Caridad copper-molybdenum deposit near Nacozari in Sonora State. Construction of an open pit mine, mill, smelter, and refining complex was estimated to cost over $300 million. Reserves were estimated at 700 million tons of ore having an average grade of 0.76% copper and 0.016% molybdenite. The concentrator will process ore at a rate of 60,000 tons per day. Parsons-Jurden Co., a Division of Ralph M. Parsons Co., was the contractor. Work projects underway included construction of an air strip and a 50-mile road from Nacozari to the mine site.

Mongolia.—A legend describing a mysterious cauldron of copper hidden beneath the Erdenetyin Ovo (Treasure Hills) was reportedly responsible for discovery of a vast copper-molybdenum ore body in Mongolia. The deposit, located about 200 miles northwest of Ulan Bator, in the remote mountain ranges along the Soviet-Mongolian border, was being developed as an open pit mine.

Numerous expeditions were conducted into the remote area in search of the copper cauldron and to prospect for other minerals, but results proved disappointing. In the late 1960's, a team of Mongolian and Czechoslovakian geologists conducted an intensive petrographic study of the igneous rocks in the area and subsequently made the initial discovery of copper and molybdenum mineralization. Development currently underway lends credence to the legend.

It was apparent that the remoteness of the deposit would necessitate huge expenditures for construction of a mineral plant, connecting railroad, and electric power transmission lines to Erdenet. In 1973, the Mongolian Government negotiated a joint venture agreement with the U.S.S.R. to develop the deposit. The Soviets would provide most of the funds and technological assistance in return for future production of copper and molybdenum. The mine reportedly will produce at a rate of 16 million tons of ore per year. Production was scheduled to start in 1978. A concentrator, warehouse, other ancillary facilities, and townsite were in various stages of construction.

Netherlands.—AMAX, Inc., planned to increase capacity to 30 million pounds at its molybdenum conversion plant near Rotterdam. The expansion, costing $15 million, included installation of an additional roaster, construction of a sulfuric acid plant, and building of warehouses and other ancillary facilities. The increase in capacity was required to meet anticipated rising demands for molybdenum products in Europe. Completion of the facility was scheduled for 1975.

Peru.—Empresa Minera del Peru (Mineroperu) initiated development of the Toromocho copper-molybdenum deposit located about 120 miles east of Lima. The project, costing an estimated $730 million, will include additional drilling and testing of the ore deposit, removal of over 14 million tons of overburden, and construction of a mine-mill smelter-refining complex. The mineral complex was expected to produce yearly over 80,000 tons of copper metal and about 4 million pounds of molybdenum. Completion of the entire project was scheduled for 1981. The Government of Peru acquired the deposit from Cerro de Pasco Corp. in 1973 and assigned it to Mineroperu for development.

TECHNOLOGY

Industrial and institutional research in 1974 was conducted to discover new uses for molybdenum. Researchers studying industrial applications for molybdenum investigated its use in corrosion, high temperature, nuclear, and electronic applications. Scientists also explored many other fields of essential molybdenum research, such as, extractive, and physical metallurgy of the metal and alloys.

The Bureau of Mines produced molybdenum alloys with good strength properties at elevated temperatures by the powder metallurgical internal oxidation method.[2] Molybdenum was blended with reactive powder of 0% to 10% zirconium-molybdenum ($ZrMo_2$). The effects of composition, blending procedure, and sintering conditions on strength properties at elevated temperatures were evaluated in the report. Strengthening was attributed to zirconium in solid solution with molybdenum and to the presence of submicrometer particles of ZrO_2.

A process for the preparation of molybdenum metal by electrolysis of molybdenum carbide in a molten salt electrolyte was described.[3] An optimum metal recovery rate was obtained in an inert atmosphere electrolytic cell utilizing a KCL-K_3 $MoCl_6$ electrolyte. The process yielded a total metal recovery of 71% at an average current efficiency of 60%. The metal purity exceeded 99.9% and the hardness was in the range of 150 to 160 diamond pyramid hardness (DPH). This experiment demonstrated the feasibility of electron extraction of molybdenum from its carbide. The electrolyte proved superior to others for sustained electro-extraction.

The hot corrosion behavior of a series of wrought nickel-base superalloy specimens was investigated as a function of molybdenum content ranging from 0 to 8 weight percent and the results were published.[4] The specimens were heated in a burner rig containing a solution with 5-part-per-million salt concentration. Molybdenum significantly reduced the amount of hot corrosive attack at 1,600° F on some nickel- base alloys containing chromium and aluminum. Molybdenum had little effect at 1,800° F on corrosion resistance on the specimens except those containing 6% aluminum. Sulfidation attack at 1,600° F was greater than at 1,800° F on nickel-base alloys containing chromium and aluminum. The sulfidation attack was greater at 1,800° F on nickel-base alloys containing chromium, aluminum, and titanium.

The effect of dextrin on molybdenum surface properties was investigated experimentally by measuring the Zeta potential, absorption, densities, contact angles, Hallimond tube flotation, and oil flotation.[5] It was ascertained that the absorption of dextrin on molybdenum is independent of pH and follows a Langmuir-type of behavior. It appears to result from hydrophobic bonding, with the polymer molecule displacing the water molecule at the interface. The Zeta potential of molybdenite was reduced in absolute magnitude with dextrin due to movements of the slipping plane farther out into the solution by the absorption of large nonionic polymer molecules. Dextrin was a very effective depressant for the air flotation of molybdenite in the absence of a collector, whereas, it does not effectively depress molybdenite in an oil flotation process using iso-octane. This must result from the complex contribution of electrical double layer repulsion, van der Waal's attraction, and hydration effects, together with possible partial solubility of dextrin in the oil phase or with displacement of absorbed dextrin by the oil phase.

Molybdenum metal was produced from molybdenum disulfide by two different extraction processes and the results were published.[6] One process utilized two steps consisting of (1) aluminothermic reduction of molybdenum disulfide and (2) conversion of this disulfide to high-purity molybdenum metal by fused-salt electrorefining. Another process utilized a direct recovery of molybdenum from molybdenum disulfide-carbon anodes by fused-salt electrorefining. In the electrorefining of thermit metal, a metal recovery of 85% and an average current efficiency of 70% was obtained. Electrolysis of molybdenum disulfide-carbon anodes resulted in a metal recovery of 82% at an average current efficiency of 50%. Both extraction processes yielded molybdenum of comparable purity.

Several types of molybdenum organic-inorganic corrosion inhibitors were tested and the results were reported.[7] In view of increasing water pollution restrictions, new chemical compound corrosion inhibitors were designed to provide effective control on the quality of industrial effluents. Molybdenum corrosion inhibitors facilitated anodic passivation, and the transition between active and passive potentials comprised several well-defined states which were registered in potentiostatic measurements. Molybdates have an advantage over traditional inhibitors because they are nontoxic. Some molybdate salts in diluted solutions inhibit corrosion as efficiently as chromate and nitrite salts.

Physical properties of newly developed corrosion resistance stainless steel containing molybdenum were published.[8] The report reviews some of the recent developments in molybdenum-containing stainless steels and alloys. Other steels discussed were ferritic, austenitic, austenitic-ferritic stainless steels, and other higher alloy materials. Recent progress in developing nickel-molybdenum and nickel-chromium-molybdenum alloys also was evaluated. Molybdenum improves the corrosion resistance of both stainless steels and nickel-base alloys, especially under reducing conditions and in the presence of chlorides. The new ferritic stainless steel was expected to solve stress-corrosion cracking problems under many plant environments.

Among the patents issued were several, concerning beneficiation, roasting, refining, and leaching. Patents granted were for froth flotation of copper sulfide ores which contain molybdenite and other sulfide minerals;[9] for recovery of volatized rhenium from molybdenite roaster gases;[10] for froth flotation recovery of molybdenite from copper sulfide ore using xanthate as a depressant;[11] for lowering the lead impurity content of molybdenum concentrate;[12] for extraction of molybdenum and rhenium from molybdenite containing ore with an ammonium persulfate solution;[13] for refining of molybdenite by roasting then subsequent leaching;[14] for upgrading of low-grade molybdenite containing a nonsulfide gangue by roasting and the calcine leach method;[15] for prevention of foaming in the cleaner step of the froth flotation of molybdenum;[16] for solvent extraction recovery of molybdenum, rhenium, and selenium from acqueous off-gas scrubber in molybdenite roasting;[17] for recovery of molybdenum trioxide ores containing molybdenum disulfide;[18] for electrowinning molybdenum and rhenium from a slurry of finely divided ore;[19] for recovering molybdenum and rhenium from amine or quaternary ammonium extractant;[20] for recovery of molybdenum from an alkali solution;[21] for recovery of molybdenum in a three-chambered electrolytic cell;[22] and for leaching molybdenum concentrate of solubilized lead.[23]

Natural Gas

By Gordon W. Koelling [1] and Leonard L. Fanelli [2]

Marketed production of natural gas in the United States declined approximately 1.0 trillion cubic feet (Tcf) to 21.6 Tcf in 1974. This 4.6% decrease, the first since 1938, followed the rapid depletion of the Nation's proved natural gas reserves during the recent years.

Total consumption of natural gas (including extraction losses) in 1974 was 22.1 Tcf, 3.7% less than during 1973. All categories of consumption registered declines during 1974. The industrial sector, the dominant user of natural gas, experienced the greatest decline, 438 billion cubic feet (Bcf), and the electric utilities and residential sectors registered decreases of 176 Bcf and 93 Bcf, respectively. Declining consumption in the industrial and electric utility sectors during 1974 was related to a 6.9% increase in the curtailment of firm deliveries by pipeline companies, and to a general decline in the Nation's economic activity. A warmer than normal winter and conservation efforts contributed to the decrease in residential use.

Table 1.—Salient statistics of natural gas in the United States

	1970	1971	1972	1973	1974
Supply:					
Marketed production [1] million cubic feet	21,920,642	22,493,012	22,531,698	22,647,549	21,600,522
Withdrawn from storage do	1,458,607	1,507,630	1,757,218	1,532,820	1,700,546
Imports do	820,780	984,548	1,019,496	1,032,901	959,284
Total do	24,200,029	24,985,190	25,308,412	25,213,270	24,260,352
Disposition:					
Consumption do	22,045,799	22,676,581	23,009,445	22,965,914	22,110,623
Exports do	69,813	80,212	78,013	77,169	76,789
Stored do	1,856,767	1,839,398	1,892,952	1,974,324	1,784,209
Lost in transmission, etc do	227,650	388,999	328,002	195,863	288,731
Total do	24,200,029	24,985,190	25,308,412	25,213,270	24,260,352
Value at wellhead:					
Total thousand dollars	3,745,680	4,085,482	4,180,462	4,894,072	6,573,402
Average cents per thousand cubic feet	17.1	18.2	18.6	21.6	30.4

[1] Marketed production of natural gas represents gross withdrawals less gas used for repressuring and quantities vented and flared.

Exports of 77 Bcf in 1974 were almost the same as in 1973. Approximately 65% of total 1974 exports were shipped from Alaska to Japan as liquefied natural gas (LNG). The remaining exports, which were transported by pipeline, were almost equally divided between Canada and Mexico.

Natural gas imports declined 7.1% to 959 Bcf in 1974. Essentially, all of this gas was shipped from Canada via pipeline. Imports from Mexico were insignificant and no LNG shipments were received.

Proved reserves of natural gas declined 5.2% from 250.0 Tcf at yearend 1973 to 237.1 Tcf by yearend 1974 as annual discoveries failed to equal production for the sixth time in the last 7 years. New reservoir discoveries in old fields and new field discoveries during 1974 totaled 4.2 Tcf, and extensions to known fields accounted for 5.8 Tcf. Revisions of previous reserve estimates resulted in a net reduction of 1.3 Tcf.

---

[1] Mineral specialist, Division of Petroleum and Natural Gas.

[2] Survey statistician, Division of Fuels Data.

The average wellhead value of natural gas increased 40.7% to 30.4 cents per thousand cubic feet (Mcf) in 1974. During the same year, the average retail price for gas delivered to consumers rose 22.3% to 89.4 cents per Mcf.

Efforts to supplement natural gas supplies through the gasification of liquid fuels continued. Eleven such synthetic gas plants were operational, and three were planned as of yearend 1974.

Five pilot projects for the development and testing of processes for the production of high-Btu gas from coal were operational or under construction at yearend 1974. A Bureau of Mines experimental coalbed degasification project was also in progress during the year. Several gasification projects involving biomass conversion were also under development.

Research involving fracturing techniques to stimulate flow from economically submarginal gas reservoirs was also in progress.

The Federal Power Commission (FPC), which regulates the sale, transportation, and price of gas moved in interstate commerce, established a single uniform national base rate for interstate natural gas sales by producers in an opinion issued June 12, 1974. This rate applies to gas from wells commenced since January 1, 1973, and to new dedications of gas to interstate commerce since that date. The base rate of 42 cents per Mcf established by the June 12 opinion was raised to 50 cents per Mcf on December 4, 1974.

The Office of Pipeline Safety (OPS), which is responsible for safety regulation of natural gas pipelines, reported that the total number of pipeline failures increased 8.3% during 1974. Damage by outside forces was the cause of 69.7% of total failures. Data on pipeline failures are shown in table 2.

Federal gas pipeline safety standards contained in the Code of Federal Regulations (CFR) 49, Part 192, were amended in 1974 to extend the period for continuing odorization of gas in certain transmission lines until January 1, 1977. Notices were also issued proposing to amend the standards with regard to qualifications for use of plastic pipe, improved requirements for pipe welding and weld inspections, telemetering pressures to provide advance warnings of pipeline failures, new standards for offshore lines, and a clearer definition of gathering lines.

DOMESTIC PRODUCTION

Gross withdrawals of natural gas, including marketed production, gas returned to the formation for pressure maintenance and that vented or flared, totaled 22.8 Tcf in 1974, approximately 5.1% less than 1973. Marketed production declined 4.6% to 21.6 Tcf during 1974, and the quantity of gas used for repressuring decreased 7.8% to about 1.1 Tcf. Data on gross withdrawals and disposition of natural gas appear in table 4.

Gross withdrawals from gas wells declined 3.6% in 1974 to 18.7 Tcf, and gas withdrawals from oil wells dropped 11.0%. Increased gross withdrawals were registered by 15 of the 31 producing States ,but the quantities involved were small. The largest gain, 30.7 Bcf, was in New Mexico, the only major producing State to record an increase.

The combined decrease in gross withdrawals registered by the three largest producing States; Texas, Louisiana, and Oklahoma; was equivalent to approximately 93% of the country's total net decline in 1974. Oklahoma registered a decline of 7.0%, most of which was accounted for by decreased gas withdrawals from oil wells. Louisiana showed a decline of 6.7%, over one-half of which was accounted for by a drop in production from gas wells, and Texas registered a decrease of 4.6%, most of which was accounted for by a decline in gas well production.

Almost three-fourths of total 1974 marketed natural gas production was from Texas and Louisiana. Marketed production data for the leading producing States are shown in the following tabulation:

State	1974 marketed production (Bcf)	Percent of change from 1973	Percent of total U.S. marketed production in 1974
Texas	8,171	−4.0	37.8
Louisiana	7,754	−5.9	35.9
Oklahoma	1,639	−7.5	7.6
New Mexico	1,245	+2.1	5.8
Kansas	887	−.1	4.1
California	365	−18.7	1.7
Wyoming	327	−3.7	1.5
Others	1,213	+.9	5.6
Total	21,601	4.6	100.0

Gas well completions increased 14.3% to 7,239 in 1974. Approximately 40.7% of the total net increase in gas well completions was accounted for by Texas where development of the Laredo field was partially responsible for increased activity. Another 12.2% of the total increase was registered by Ohio where most of the wells completed were relatively shallow. A summary of gas and oil well completions appears in table 5.

Completions of exploratory gas wells in 1974 increased 32.7% to 1,194, as shown in table 6. Texas accounted for 47.1% of these completions.

Data on gas well completions include condensate wells. The latter are wells which produce from high-pressure natural gas reservoirs, some of which contain considerable quantities of liquid hydrocarbons in the pentanes and heavier range described generically as "condensate."

The number of gas and gas condensate wells producing at yearend 1974 totaled 126,329. This was an increase of 1.7% over the 1973 yearend total, but was 12.6% less than the number of wells producing at yearend 1969.

CONSUMPTION AND USES

Consumption of natural gas (wet) in 1974 totaled 22.1 Tcf, a 3.7% decrease from 1973. Gas delivered to consumers declined 3.8% to 19.1 Tcf during 1974 when it accounted for 86.3% of total consumption. Of the remainder, 6.7% was used as lease and plant fuel, 3.0% was used for pipeline fuel, and 4.0% was accounted for by extraction losses (shrinkage) at gas processing plants. Data on total natural gas consumption and on deliveries to consumers, by type of consumer, are presented in tables 8-9.

Residential use declined 1.9% to 4,786 Bcf in 1974 when it accounted for 25.1% of total deliveries to consumers. The decrease in residential use, which was accompanied by a 2.1% increase in the number of consumers, reflected a warmer than normal winter season and the positive results of conservation efforts.

Data on the number of residential customers by Census Regions for the years 1964, 1973, and 1974 are shown in the following tabulation:

Census regions	Residential consumers (thousands)		
	1964	1973	1974
New England	1,491	1,603	1,623
Middle Atlantic	7,357	7,713	7,779
East North Central	7,813	9,386	9,439
West North Central	2,945	3,399	3,519
South Atlantic	2,835	3,513	3,569
East South Central	1,641	1,959	2,001
West South Central	3,919	4,575	4,811
Mountain	1,402	2,021	2,151
Pacific	5,172	6,476	6,617
Total	34,575	40,645	41,509

The use of gas by the commercial sector declined 1.1% to 2,263 Bcf in 1974 despite a 4.3% increase in the number of customers. This sector accounted for 11.9% of total deliveries to consumers.

The industrial sector remained the dominant user of natural gas, accounting for 43.5% of 1974 deliveries to consumers. However, total consumption by this sector declined 5.0% to 8,306 Bcf during the year. Most of the gas used by industry was consumed as fuel. Primary metal industries, which used an estimated 1,060 Bcf, and petroleum refineries, which used 1,040 Bcf, were the principal fuel consuming industrial sectors. Other important industrial users of gas for fuel included the nonmetallic, paper, and food products sectors. The principal nonfuel use of gas involved the chemicals industry which used it as a feedstock, primarily in the production of fertilizers and plastics. In 1974, an estimated 1,490 Bcf was used by the chemicals industry both as feedstock and for fuel.

Electric utility use of natural gas continued to decline in 1974 when consumption by this sector dropped 4.9% to 3,429 Bcf. The decrease was greatest in the Pacific region where consumption declined 164 Bcf. Consumption rose 95 Bcf in the West South Central region and small increases occurred in the New England and East North Central regions.

The decline in natural gas supply dur-

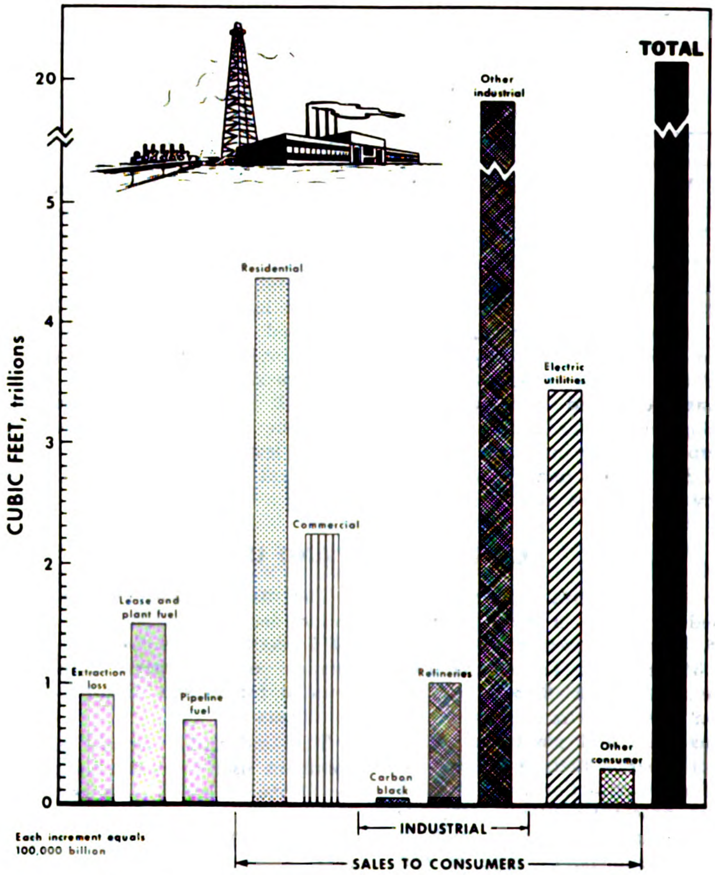

Figure 1.—Disposition of natural gas consumed in the United States by principal use.

ing 1974 forced many gas distribution companies to deny service to new customers and to curtail supplies to some existing users. FPC reported that net curtailments of actual firm net requirements for the year April 1974 through March 1975 totaled 2,013 Bcf, a deficiency of 13.6%. Net interruptible curtailments for the same period were reported at 196 Bcf, a deficiency of 36.6%. Firm curtailments for the year ending March 1974 were 6.9% higher than those for the preceding period and interruptible curtailments showed little change. Data on curtailments are shown in tables 11-12.

The mileage of field and gathering, transmission, and distribution pipelines in service at the end of 1974 was up 1.3% from 1973. Most of this increase was accounted for by a 1.8% increase in the mileage of gas distribution mains which reflected the expansion of the gas utility industry into less densely populated areas. Data on the nations natural gas pipeline network are shown in the following tabulation:

Mileage, natural gas pipelines

	1962	1972	1973	1974
Field and gathering	58.7	67.1	66.2	67.0
Transmission	196.4	r 258.5	263.6	263.5
Distribution	428.1	r 624.6	634.6	646.2
Total	683.2	r 950.2	964.4	976.7

r Revised.

RESERVES

Discoveries of natural gas failed to equal production during 6 of the last 7 years, and proved reserves declined 19% during the period. In 1974, the quantity of gas discovered was considerably less than that produced, and proved reserves dropped 5.1% from 250.0 Tcf at yearend 1973 to 237.1 Tcf by yearend 1974 according to the Natural Gas Reserves Committee of American Gas Association (AGA).

Additions to proved reserves reported for the United States in 1974 aggregated nearly 8.9 Tcf, approximately 37% more than in 1973. About 30% of net additions to reserves in 1974 were offshore in the Gulf of Mexico. The largest addition to reserves, 5.8 Tcf, involved extensions to known fields. More than 55% of the 2.2 Tcf total for new reservoir discoveries in old fields (including offshore) were in Louisiana. New field discoveries totaled approximately 2.0, over 71% of which was accounted for by Louisiana and Texas. On the negative side, revisions of previous reserve estimates resulted in a net reduction of 1.3 Tcf. Details on proved reserves of natural gas in the United States are shown in table 16.

There were some net increases during 1974 in the reserves of natural gas in 15 States. However, significant increases occurred in only three States; Alaska with 0.22 Tcf, Alabama with 0.18 Tcf, and Florida with 0.16 Tcf. Reserves of the principal gas-producing States declined sharply. Texas gas reserves declined 6.4 Tcf, or 7.5%, and reserves in Louisiana decreased 5.1 Tcf, or 7.4%.

Natural gas reserves committed to interstate pipelines declined in 1974 for the seventh consecutive year. Dedicated domestic reserves dropped 10.3% in 1974, and domestic gas produced and purchased by interstate pipelines declined 5.9% from the 1973 total of 13.7 Tcf to 12.9 Tcf in 1974. The reserve-production ratio for interstate reserves dropped from 9.8 at yearend 1973 to 9.3 by yearend 1974. Additional data are shown in the following tabulations:

Preliminary summary of domestic natural gas reserves, of interstate natural gas pipeline companies

(Billion cubic feet at 14.73 psia at 60° F)

Figure 2.—Trends in annual additions to natural gas reserves.

PRODUCTIVE CAPACITY

The daily productive capacity for natural gas in 1974 was estimated at 72,311 million cubic feet (MMcf) by AGA, compared with 78,231 MMcf in 1973, a decline of 7.6%. Nonassociated gas productive capacity fell 6.3% to 60,091 MMcf per day, and associated-dissolved gas productive capacity declined 13.2% to 12,220 MMcf per day in 1974.[3]

---

[3] The productive capacity of natural gas from nonassociated reservoirs is defined as the maximum daily rate at which such gas can be produced from natural reservoirs under specified conditions on March 31 of any given year. The determination of productive capacity on March 31 of any given year is based on proved reserves of nonassociated gas reservoirs as of the preceding December 31. The productive capacity of associated dissolved gas is based on the productive capacity of crude oil and the estimated producing gas-oil ratios which would result from such capacity operation during the first 90 days of a given year. The productive capacity of associated gas from oil wells is usually based on the volumetric withdrawal of crude oil from related oil wells at capacity rates during the first 90 days of a given year as determined by the American Petroleum Institute (API) Committee on Reserves and Productive Capacity.

STORAGE

The development of additional underground storage capacity for natural gas continued during 1974. Total reservoir capacity increased 1.4%, from 6,279 Bcf in 1973 to 6,364 Bcf by yearend 1974. The number of underground storage facilities was increased from 360 in 1973 to 367 in 1974. These storage facilities are located in 26 States.

Most storage reservoirs are depleted gasfields. Of the total 367 storage reservoirs in use, 288 or 78% were of this type. Most of these reservoirs are located in the northeastern United States, primarily in the oldest oil and gas producing States. In Pennsylvania, where oil production dates back to 1859, nonassociated gasfields converted to storage facilities totaled 68 at yearend 1974. West Virginia had 35 reservoirs of this type as of the same date. The second largest concentration of these storage reservoirs was in the midwest, primarily in Michigan where 34 were in use.

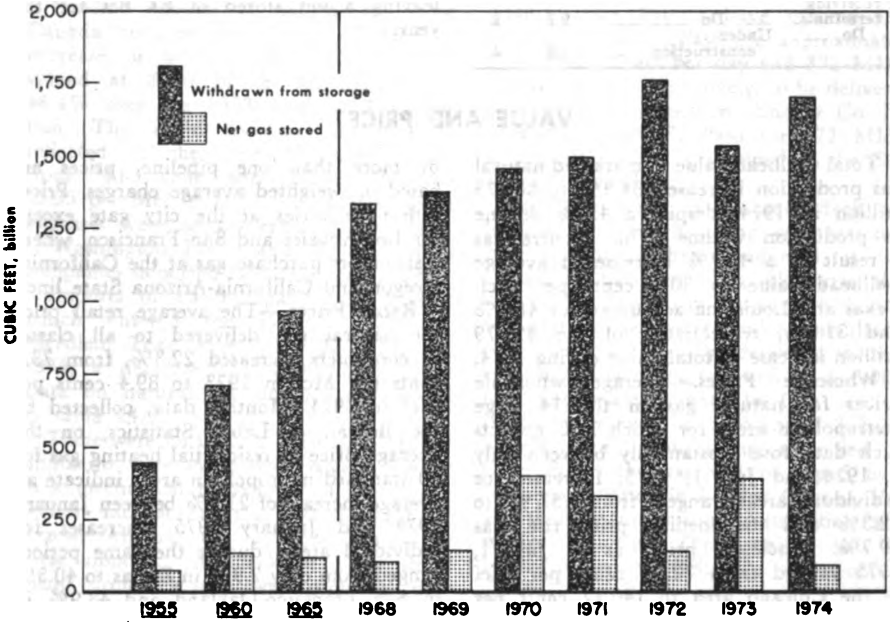

Figure 3.—Trends in net gas stored underground in U.S. storage fields.

The development of underground storage reservoirs has been an important factor in meeting peak natural gas demand, particularly in the residential house heating market in which there is a high degree of seasonal variation. There is a concentration of underground storage facilities relatively close to the largest markets for residential heating. Illinois had 612 Bcf of natural gas stored in 31 reservoirs and Pennsylvania had 557 Bcf stored in 68 reservoirs at yearend 1974. These two States accounted for 29.5% of the total stored gas in underground reservoirs.

In addition to underground storage there has been a marked growth in the aboveground storage of natural gas which has been liquefied by lowering its temperature. When natural gas is converted to a liquid by reducing its temperature to −258° F (−161° C), it occupies only 1/620 of the space necessary for conventional vapor storage. LNG storage is used for peak shaving purposes during the high-consumption, low-temperature winter months.

The following tabulation summarizes LNG storage data:

Facility	Status	Capacity (Bcf)	Number of plants
Peak shaving	Operational	51.6	54
Do	Under construction	6.7	7
Large satelite	Operational	5.2	20
Do	Under construction	2.5	8
Small satelite	Operational	.2	81
Import receiving terminals	Do	9.8	2
Do	Under construction	16.2	4

Where depleted oilfields or gasfields are not available, other types of underground storage reservoirs have been developed. For example, 51 aquifer type reservoirs were in use in 10 States at the end of 1974. Illinois was the leading State with 22, and Indiana ranked second with 10. Aquifer storage accounted for 22.1% of total underground storage capacity at yearend 1974. The increase in aquifer reservoir capacity during the year was negligible.

In 1974, the total amount of gas moved into underground storage totaled 1,784 Bcf as shown in table 19. During the same period, 1,701 Bcf was withdrawn, leaving a net stored of 83 Bcf for the year.

VALUE AND PRICE

Total wellhead value of marketed natural gas production increased 34.3% to $6,573 million in 1974, despite a 4.6% decline in production volume. This occurred as a result of a 40.7% increase in average wellhead value to 30.4 cents per Mcf. Texas and Louisiana accounted for 48.0% and 31.8%, respectively, of the $1,679 million increase in total value during 1974.

Wholesale Prices.—Average wholesale prices for natural gas in the 14 large metropolitan areas for which FPC collects such data rose substantially between July 1, 1974 and July 1, 1975. Increases for individual areas ranged from 15.7% to 92.3% and the median price rise was 29.7%. Wholesale prices as of July 1, 1975 ranged from 72.68 cents per Mcf in the Chicago area to 140.17 cents per Mcf in the Boston area.

A 7-year historical series of average wholesale natural gas prices in the 14 large metropolitan areas is shown in table 20. The wholesale prices for gas for those cities cited, are based on the effective FPC gas tariffs. In cities served by more than one pipeline, prices are based on weighted average charges. Prices reflect deliveries at the city gate except for Los Angeles and San Francisco, where distributors purchase gas at the California-Oregon and California-Arizona State lines.

Retail Prices.—The average retail price for natural gas delivered to all classes of consumers increased 22.3%, from 73.0 cents per Mcf in 1973 to 89.4 cents per Mcf in 1974. Monthly data, collected by the Bureau of Labor Statistics, on the average price of residential heating gas for 20 standard metropolitan areas indicate an average increase of 21.7% between January 1974 and January 1975. Increases for individual areas, during the same period, ranged from only 2.9% in Dallas to 40.3% in San Francisco-Oakland and 43.9% in Houston, where much of the current supply is obtained under relatively recent, high-priced intrastate contracts. A historical summary of average residential heating gas prices in 20 Standard Metropolitan Statistical areas appears in table 21.

FOREIGN TRADE

Exports of natural gas totaled 77 Bcf in 1974, about the same amount as in 1973. Of the total volume 65.5% was shipped from Port Nikiski, Alaska, to Japan as LNG. Exports via pipeline were almost equally divided between Canada and Mexico.

The LNG exported to Japan in 1974 totaled 50.26 Bcf valued at $37 million, compared with 48.35 Bcf valued at $27 million in 1973. The Alaskan LNG was exported rather than shipped to the lower 48 States for the following reasons: (1) There are no receiving terminals for

LNG tankers on the U.S. Pacific coast, and (2) Federal Maritime law requires U.S. flagships for all interstate seaborne trade, but no U.S. flag LNG tankers exist. Statistics on LNG exports for 1974 are shown in table 22.

Exports via pipeline to Canada in 1974 totaled 13.3 Bcf compared with 14.8 Bcf in 1973, a decline of 10.5%. Detroit was the exit point for most of these exports.

Natural gas exports via pipelines to Mexico continued to decline from 14.0 Bcf in 1973 to 13.3 Bcf in 1974. Comparisons of exports in 1973 and 1974 are shown in table 23.

Pipeline imports of natural gas from Canada declined in 1974 to 959 Bcf, a decrease of 6.6%. These imports were valued at $530 billion an increase of 48.4% over the 1973 total of $357 billion. The rapid increase in value is reflected in the average price of gas from 34.83 cents per Mcf in 1973 to 55.35 per Mcf in 1974. The greater price increases were on gas entering the States of Washington, Idaho, and Montana. Nine companies imported Canadian gas in 1974.

Imports of natural gas from Mexico, which entered the United States at McAllen, Tex., were only 222 MMcf in 1974, a decrease of 86.4% from 1973. Data on natural gas imports are shown in table 24.

There were no LNG imports in 1974. No shipments were made from Algeria owing to a mechanical breakdown of the liquefaction facilities at the LNG-1 plant at Arzew, Algeria, the previous source of these imports. The lack of LNG shipments from Canada was probably due to the full utilization, by the Canadians, of the output of the Montreal liquefaction facilities from which LNG was previously shipped to the United States by truck.

Two major LNG import receiving terminals were under construction during 1974, one on Elba Island near Savannah, Ga., and another at Cove Point, Md. These terminals will receive LNG in connection with the El Paso Natural Gas Co. contract with Société Nationale pour la Recherche, la Production, le Transport, la Transformation, et la Commercialisation des Hydrocarbures (SONATRACH), Algeria's National Oil and Gas Co. This 25-year contract, which has been approved by FPC, calls for the delivery of a quantity of LNG, equivalent to 1 Bcf of gas per day. Deliveries under this contract are expected to begin in 1977. The Columbia Gas System and the Consolidated Natural Gas System have entered into contracts with El Paso for approximately 319 MMcf of gas per day and 372 MMcf of gas per day, respectively, to be delivered to Cove Point. Southern Energy Co. has contracted with El Paso for 372 MMcf of gas per day to be received at the Elba Island terminal.

At Cove Point, a concrete deck unloading facility was being constructed a mile offshore. When completed, it will consist of two unloading platforms that will extend one-half mile along the channel allowing two tankers to unload simultaneously. The LNG will be delivered through two unloading lines enclosed in a 6,000-foot underwater tunnel to four onshore storage tanks with a capacity of 375,000 barrels each. After being regasified at Cove Point, the gas will be piped to a compressor station in Loudon County, Va., and then to transmission, distribution, and storage facilities. The terminal will be jointly owned by Columbia and Consolidated.

The receiving facility on Elba Island being built by Southern Energy Co., will have a single offshore berth that will be linked to the island by a 300-foot long trestle. Other proposed LNG projects are awaiting FPC approval.

WORLD REVIEW

World marketed production of natural gas continued to climb in 1974 when it totaled 47.1 Tcf. The United States accounted for 21.6 Tcf or 45.8% of this total. Data on world production of natural gas is shown on table 25.

The U.S.S.R. was second to the United States, accounting for 19.6% of world production. During 1974, marketed production in the U.S.S.R. was estimated to have been 9.2 Tcf, an increase of 10.6% over that of 1973. Combined exports to West Germany, Italy, Austria, and Finland totaled 210 Bcf in 1974. The 560-mile

U.S.S.R.-Bulgaria pipeline went onstream in August 1974, with an initial capacity of 97 MMcf of gas per day and reportedly will increase to 290 MMcf per day within 2 years. Also, nearing completion was a new pipeline to Hungary which will initially transport 97 MMcf of gas per day, and is expected to handle 340 to 390 MMcf per day by 1980.

A conditional $400 million agreement was signed in late 1974 by the U.S.S.R. and Japan along with two U.S. companies, El Paso Natural Gas Co. and Occidental Petroleum Corp., for the development of gasfields in Siberia. Under terms of the agreement, Japan would extend $100 million in credit upon approval of a $100 million loan from the U.S. Export-Import Bank. The pact calls for the delivery of about 1,900 MMcf of gas per day over a 25 year period, to be shared equally by Japan and the U.S. companies. El Paso would receive 75% of the U.S. share and 25% would go to Occidental. The gas would be liquefied for shipment to Japanese ports and to the U.S. west coast.

In Canada, which ranks third in natural gas production, marketed production totaled 3.0 Tcf in 1974, a decline of 2.6% from that of 1973. More than 85% of total Canadian production came from the Province of Alberta; British Columbia accounted for more than 11.5%. Exports to the United States totaled 959 Bcf, almost 40% of total production.

Net additions to gas reserves during 1974 of 4.2 Tcf increased total proved reserves to 56.7 Tcf, the largest increase since 1969. The inclusion, for the first time, of Mackenzie Delta reserves and successful exploration in Alberta were the most prominent contributions to this increase.

Although exploration declined in 1974, several significant gas discoveries were made. One of these discoveries, the Taglu field on Richards Island in the Mackenzie Delta area, contains upwards of 3 Tcf of gas. The Shell Niklintgak discovery, located about 11 miles southwest of the Taglu fields, also in the Mackenzie Delta area, tested up to 16 MMcf of gas per day. Preliminary estimates place reserves of this field at about 1 Tcf of gas and about 80 million barrels of oil. Three significant east coast offshore discoveries were made in 1974; two on the Labrador Shelf and one off the east tip of Prince Edward Island.

Exploration in the Arctic Islands declined in 1974, and no new gas discoveries were made. A major extension of more than 25 miles was added to the already sizable Drake Point field on the west coast of Melville Island. Drake Point is one of five substantial gas fields previously discovered by Panarctic Oil Ltd. The other four are Kristoffer Bay, Thor, Hecla, and King Christian. Sizable gas reserves were also discovered previously in two locations on King Christian Island by Dome Petroleum Ltd.

Three separate consortiums composed of pipeline and oil companies were in the process of investigating the feasibility of building pipeline facilities from the Canadian Arctic to market areas during 1974.

Canadian Arctic Gas Study, Ltd. (CAGSL), a consortium of U.S. and Canadian companies, filed an application in March 1974, with the National Energy Board (NEB) to construct a $5.7 billion pipeline which would bring Mackenzie Delta and Alaska gas to Southern markets.

The Alberta Gas Trunk Line Co., Ltd., late in 1974, withdrew from CAGSL and was joined by Westcoast Transmission Co., Ltd. as a partner in Foothills Pipe Lines Ltd. This company filed application to build a pipeline (Maple Leaf pipeline) to transport only Canadian natural gas from the Mackenzie Delta.

Marketed production in the Netherlands, Western Europe's largest gas producer and exporter, totaled 3.0 Tcf in 1974, an increase of 18.5% over 1973. The Netherlands gas reserves were estimated at 77 Tcf (including 17 Tcf offshore) in 1974, a decline of 7.8 Tcf from the 1973 estimate. Groningen field, with the largest share of gas reserves, produced over 95% of the Netherlands total output. Exploration activity was increased offshore in 1974, and production licenses were granted to two North Sea offshore gasfields. In 1974, the first offshore gas was delivered through a new pipeline to West Germany. Natural gas exports went principally to West Germany, Belgium, and France. A pipeline to Italy, completed in 1974, will supply 580 MMcf of gas per day to that country for 20 years, and about 50 MMcf of gas per day to Switzerland.

Romania's 1974 marketed production

was estimated at 1.0 Tcf, an increase of 3% compared with 1973. Most of the gas produced was used domestically. A tentative agreement, signed in 1974 with Petróleos Mexicano (Pemex), will allow Romania to use Pemex technology for exploration in the Black Sea. Efforts were underway to attract the interest of U.S. firms in providing offshore technology.

The North Sea is one of the fastest developing natural gas areas in the world. Although exploration continued at a high rate during 1974, emphasis is turning toward development and production. Marketed production, from five fields in the United Kingdom's portion of the North Sea, rose 13.9%, from 1.0 Tcf of gas in 1973 to 1.2 Tcf in 1974. Upon completion of a 700-mile pipeline under construction, an additional 2,000 MMcf of gas per day will be available from the Brent field and the British portion of the Anglo-Norwegian Frigg field. The United Kingdom's 1974 reserves were estimated at over 44 Tcf.

Norway's proved reserves, most of which were in the offshore Ekofisk oil and gasfield, totaled 24.7 Tcf. During 1974, a 270-mile, 36-inch gas pipeline was completed from the Ekofisk field to a 2,200-MMcf-per-day processing plant at Emden, West Germany. Beginning in 1975, gas processed by this plant will be distributed to West German, French, Dutch, and Belgian companies.

Marketed production in Algeria totaled 211 Bcf in 1974, an increase of 26% over 1973. Algeria's State-owned company, SONATRACH, projects annual export sales of nearly 2.85 Tcf by 1980. Approximately 85% of these exports are expected to be in the form of LNG. In 1974 Algeria's third LNG plant was under construction at Bethioua, near Arzew. The initial plans are for a capacity of 1 Bcf of gas per day.

A 25-year contract between SONATRACH and Italy's State-owned Ente Nazionale Idrocarburi (ENI) calls for the delivery of 1 Bcf of gas per day via pipeline. The 1,550-mile pipeline, portions of which will cross the Mediterrean Sea to Italy, will start at Hassi R'Mel gasfield in Algeria, and is scheduled for completion in 1978. ENI completed the first stage of the line, a section in the Messina Straits, during 1974.

SONATRACH continued negotiations during 1974 with several European countries to provide long-term supplies of LNG.

TECHNOLOGY

Predicted shortages of natural gas have stimulated Government and industry research in coal gasification. Five pilot projects for the development and testing of processes for the production of high-Btu gas, similar to pipeline-quality natural gas, from coal were operational or under construction at yearend 1974. Some research was also in progress for the development of a process for the production of low-Btu gas from coal.

A Bureau of Mines experimental coalbed degasification project involving a methane gathering system installed in a coal mine near Bula, W. Va., delivered 170 MMcf of natural gas to Consolidated Gas Supply Corp. in 1974. However, the rate of flow from this project declined 15% during the year. The Bureau was in the process of tapping an 8-foot coal seam about 3 miles from the original project at yearend. These experiments were being carried out with a dual purpose; to provide additional natural gas supplies for distribution, and to reduce coal mining hazards.

Efforts to supplement natural gas supplies through the gasification of liquid fuels, principally naphtha, continued. Eleven such synthetic gas plants were operational, and three were planned as of yearend 1974.

Other gasification projects in progress involved biomass conversion. Methane was collected from sanitary landfills and sewage plants at several locations, and at least one project to produce pipeline-quality gas from animal waste by the process of anaerobic digestion was under development.

In addition to gasification schemes, research has also focused on fracturing techniques which stimulate flow from economically submarginal gas reservoirs. A massive hydraulic fracturing project initiated in the Green River Basin near Pinedale, Wyo., during 1974 was expected to utilize over 1 million gallons of frac fluid and about 3.5 million pounds of proppant sand that could create a fracture over 2,000 feet long in a low-permeability sandstone formation. Efforts were also in progress to fracture reservoirs in the nearly impermeable Upper Devonian shales of the eastern United States. These shales underlie about 12 States, including those which comprise the major northeastern markets, and are estimated to contain producible gas which may exceed the Nation's total current proved reserves.

Table 2.—Gas pipeline failures reported during 1973–74 [1]

System and cause of failure	Total number of failures		Fatalities				Injuries			
			Employees		Non-employees		Employees		Non-employees	
	1973	1974	1973	1974	1973	1974	1973	1974	1973	1974
Distribution:										
Corrosion	133	108	1	--	2	3	--	3	69	27

[1] Marketed production plus quantities used in repressuring and vented and flared.
[2] Partly estimated; includes direct losses on producing properties and residue blown to the air.
[3] Not reported separately, included under gross withdrawals from gas wells.

Source: Figures based on reports from State agencies and Bureau of Mines estimates.

[1] Includes refinery fuel use of 1,040,057 million cubic feet and 40,130 million cubic feet for carbon black production.
[2] Includes deliveries to municipalities and public authorities for institutional heating, street lighting, etc.
NOTE.—All quantities at pressure base of 14.73 psia.

Source: Federal Power Commission.

Table 10.—Production of natural gas liquids at natural gas processing plants, and disposition of residue gas in the United States in 1973–74, by State

(Million cubic feet at 14.73 psia at 60° F unless otherwise stated)

State	Total natural gas liquids and ethane production (thousand barrels)	Natural gas processed	Extraction loss (shrinkage)	Disposition of residue gas: Used at plants	Returned to formation	Vented and flared	Shipped to transmission companies	Direct deliveries to consumers	Unaccounted for	Total

XX Not applicable.

[1] Requirement volumes reported in the Apr. 30, 1975, Form 16's have been adjusted to eliminate volumes transported for others and exchanged with others.

[2] Grand Gas Corp. reported all volumes are sold to Northwest Pipeline Corp. It reported no curtailments.

[3] Sales deliveries were added to curtailments to obtain requirements.

[4] After elimination of pipeline-to-pipeline requirements.

[5] After elimination of pipeline-to-pipeline curtailments.

[1] The net difference between gas stored in and gas withdrawn from underground storage reservoirs, inclusive of adjustments and native gas transferred from other reserve categories.

[2] Preliminary net production.

[3] Gas held in underground reservoirs (including native and net injected gas) for storage purposes.

[4] Includes offshore.

[5] Included with Louisiana and Texas.

[r] Revised.

[1] In addition to this amount 293,904,669 Mcf were received from Trans-Canada Pipe Line Ltd. for transportation and 294,182,602 Mcf were redelivered to Trans-Canada at St. Clair and Sault Ste. Marie, Mich.

[2] Second port of entry is International Falls, Minn.

[3] In addition to this amount 11,878,847 Mcf were received from Trans-Canada Pipe Line Ltd. for transportation and redelivery to Trans-Canada at Baudette, Minn.

[4] Volumes and cost data include the gas imports reported by El Paso Natural Gas Co. for 1973 and the month of January 1974 after which Northwest Pipeline Corp. imported the volumes formerly imported by El Paso.

[5] In addition, Tennessee Gas Pipeline Co. exchanged 144,921 Mcf gas with Trans-Canada Pipelines Ltd. at Niagara, N.Y.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Cuba and Thailand produce crude oil and presumably natural gas, but available information is inadequate to estimate output levels and the share of gross production that is classifiable as marketed.

[2] Comprises all marketed production (see footnote 3) plus gas vented, flared, reinjected for repressuring, and used to drive gas turbines (without being burned).

[3] Comprises all gas collected and utilized as a fuel or a chemical industry raw material or for gas left in fields, including gas used in oilfields and/or gasfields as a fuel by producers, even though it is not actually sold.

[4] Apparently, natural gas that is vented and/or flared is not included in reported gross production; marketed output presented here is the difference between reported gross production and reported injection into reservoirs.

[5] Gross production not reported; marketed output has been reported in lieu of a gross production estimate because the quantity flared, vented, and/or reinjected is believed to be small.

[6] Total production is obtained from coal mines.

[7] Includes output from coal mines as follows, in million cubic feet: Czechoslovakia: 1972—12,325; 1973—11,159; 1974—11,000 (estimate); West Germany: 1972—21,612; 1973—21,577; 1974—21,612 (estimate); the Netherlands: 1972—1,236; 1973—671; 1974—300 (estimate); Poland: 1972—7,840; 1973—7,628; 1974—7,400 (estimate); the United Kingdom: 1972—3,567; 1973—4,485; 1974—4,600 (estimate); and Japan: 1972—9,358; 1973—10,806: 1974—10,900 (estimate).

[8] No marketed production reported; there probably is some small field use in both Denmark and Norway, and in the case of the latter there was extraction of natural gas liquids reported in 1973 and 1974, but available information is inadequate to make reliable estimates.

[9] Available statistics, used for both gross and marketed production, comprise marketed production plus gas injected into reservoirs for repressuring, but exclude gas vented and/or flared. In 1968 (latest available figure), gas used for repressuring constituted only 0.4% of the total. Information is inadequate to make a reliable estimate of gas vented and/or flared, but it is believed to have remained small.

[10] Includes gas injected to reservoirs for repressuring.

[11] Excluding gas used for gas lift.

[12] Data are for year ending June 30 of that stated.

[13] Includes ½ of production reported for the former Kuwait-Saudi Arabia Neutral Zone.

Natural Gas Liquids

By Ronald Prehoda [1] and Leonard L. Fanelli [2]

For the second year in a row, overall production of natural gas liquids (NGL) at natural gas processing plants declined. Production in 1974 was 616 million barrels or 3% below that of 1973 (634 million barrels). This reflected primarily the decline in availability of natural gas for processing. In 1974, nearly 1 trillion cubic feet less gas was produced.

The demand for propane was approximately 5% below that of 1973, reflecting the warmer than normal winter weather that occurred across the nation. In addition consumer awareness of the need for energy conservation and resistance to higher prices contributed to the decrease in propane demand.

NGL are products obtained from natural gas processed at natural gas processing plants. Included are ethane, liquefied petroleum gases (LPG—butane, propane, and butane-propane mixtures), isobutane, and other mixed gases. Also included in the output of these plants are natural gasolines, plant condensate, and at plants equipped with fractionators, finished products such as gasoline, special naphthas, jet fuel, kerosine, distillate fuel oil, and other finished products are obtained.

Data presented in this chapter were compiled from operating reports of plants that process natural gas. Included are all NGL, except the small volume considered to be negligible in national and State totals, recovered at pipeline compressor stations and gas dehydration plants. Plant condensate is included in NGL; field separated condensate, however, is included with crude oil. Ethane and liquefied gases such as butane and propane, recovered from the crude oil refining operations, are classed as liquefied refinery gases (LRG) and reported as refined petroleum products.

The LPG industry continued to operate under the government's mandatory allocation program (initiated in 1973) administered by the Federal Energy Administration (FEA). This program seeks to assure a continuing flow of the fuel to traditional and high-priority users such as residential and commercial. Along with allocation regulations were price controls which prescribed a maximum cents per gallon gross profit margin on fuel sold to various categories of users.

On September 27, 1974, by Presidential Proclamation 4317, the President reduced the fee on imports of NGL from 30 cents per barrel to 15.5 cents per barrel. This proclamation provided for the fee to increase to 18 cents per barrel on November 1, 1974, and to 21 cents per barrel on May 1, 1975. However, Presidential Proclamation 4341, dated January 23, 1975, established a fee of 21 cents per barrel effective February 1, 1975.

Unit value of NGL increased significantly during 1974. The 1974 output of NGL was valued at $3 billion, 40% above the 1973 level. The unit value rose 71% to $5 per barrel compared with approximately $3 per barrel in 1973.

[1] Includes isopentane, plant condensate, finished gasoline, special naphtha, distillate fuel oil, kerosine, and miscellaneous.

DOMESTIC PRODUCTION

The overall production of NGL declined for the second year in a row. Total production in 1974 amounted to 616 million barrels, 3% less than the 1973 production of 634 million barrels. Output of all categories of NGL declined with the exception of ethane. Ethane registered an increase of approximately 10 million barrels or 8.8% over that for 1973. This increase reflected the continued strong demand for this product as a petrochemical feedstock primarily for ethylene manufacture.

Of the major NGL components, natural gasoline and isopentane suffered the largest declines, which exceeded the gain in ethane production. This reduction in natural gasoline and isopentane production was attributable to the reduction in demand for gasoline blending. Gasoline demand was reduced nearly 50 million barrels from 1973 levels largely by restrictions enforced by the FEA.

The following tabulation shows the quantity and percent changes between 1973 and 1974 of the major NGL groups:

	Thousand barrels	Percent
Ethane	+9,571	+8.8
LPG:		
Propane	−6,347	−3.0
Other	−2,311	−1.8
Natural gasoline and isopentane	−13,785	−8.5
Other natural gas liquids	−5,458	−21.2
Total	−18,325	−0.3

At the beginning of 1974 there were 763 natural gas processing plants in the United States,[3] 23 fewer plants than at the beginning of 1973. Throughput capacity at natural gas plants, however, increased by 1,354 million cubic feet per day to 74,614 million cubic feet per day, an increase of 1.8%. Actual throughput was 55,624 million cubic feet per day. Over 47% of the plants were located in Texas and over 16% in Louisiana. The reduction in the number of processing plants reflected the phaseout of facilities in areas where gas supplies have been depleted.

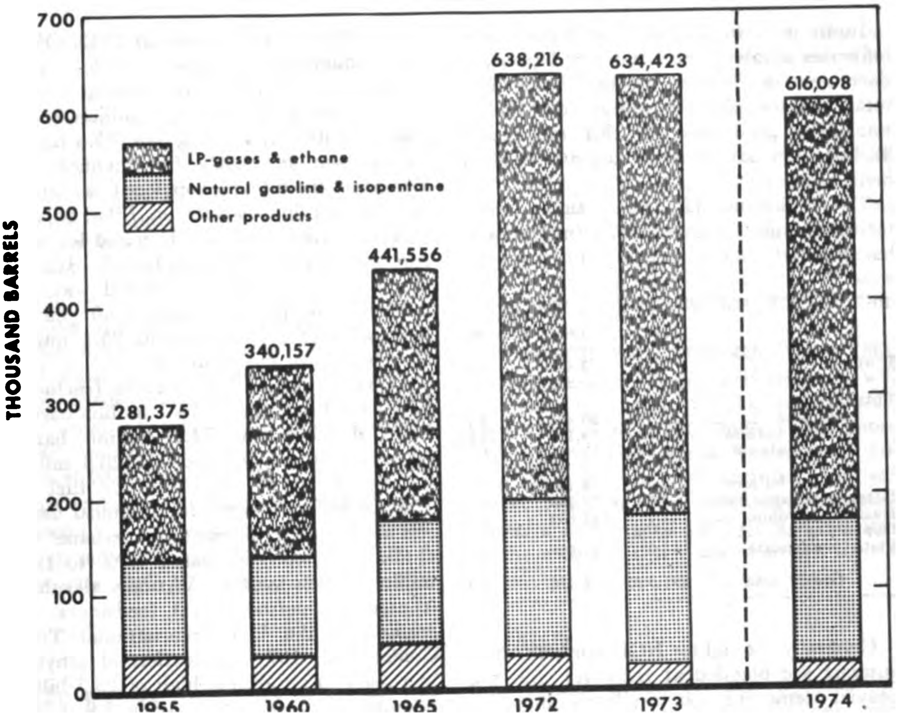

Figure 3.—Production of natural gas liquids in the United States.

RESERVES

The American Gas Association (AGA) Reserves Committee estimated that proved reserves of NGL at yearend 1974 were 6,350 million barrels. This is a decrease of 1.6% from the 1973 yearend figure of 6,455 million barrels and is the seventh consecutive year in which proved reserves declined. According to AGA data, the yearend reserve to production ratio was 8.8:1 compared with 13.4:1 in 1967 (the alltime high for proved reserves) and 8.7:1 in 1973. Only four States (Alabama, Alaska, Kansas, and Oklahoma) had net increases in proved reserves at yearend 1974. Louisiana and Texas accounted for 30% and 44%, respectively, of the total proved reserves, with significant reserves also reported in New Mexico, Kansas, and Oklahoma. Louisiana again, as last year, experienced the greatest volume reduction in reserves (110 million barrels) and also the greatest percentage decline (5.5%) among the States having major reserves.

CONSUMPTION AND USES

Input of natural gas plant liquids into refineries totaled 272.4 million barrels, a decrease of 8.4% from the 1973 level. This total run to refineries represents 44% of total NGL production. Of this total input, 32.4 million barrels were imports of plant condensate.

The following tabulation shows shipments (inputs) into refineries in thousand barrels:

	1973	1974	Percent change
Propane	2,755	3,465	+25.8
Butanes:			
Isobutane	35,723	30,829	−13.7
Normal butane	25,990	29,110	+12.0
Other butanes	11,267	13,855	+23.0
Total butane	72,980	73,794	+1.1
Butane-propane mix	4,486	2,958	−34.1
Natural gasoline	154,455	147,603	−4.4
Isopentane	5,895	--	−100.0
Plant condensate	56,911	44,596	−21.6
Grand total	297,482	272,416	−8.4

Generally the lighter NGL (propane and butane) are blended at refineries, and the heavier items are run to process units.

Domestic demand for LPG and LRG totaled 388.2 million barrels in 1974, down from 409.1 million barrels in 1973. Of the 1974 domestic demand, 269.5 million barrels was for LPG produced at natural gas processing plants, 83.2 million barrels was for LRG for fuel use and 35.6 million barrels was for LRG for chemical use. Propane (including propylene) accounted for 303 million barrels or 78% of total LPG and LRG demand. Demand for plant propane was 214.8 million barrels. Refinery propane and propylene demand was 88.2 million barrels of which 63.0 million barrels was for fuel use and 25.2 million barrels was for chemical use.

Domestic demand for butane (including butylene) decreased to 74.7 million barrels. Plant demand was 54.2 million barrels whereas refinery demand was 20.5 million barrels of which 14.1 was for fuel use and 6.4 million barrels for chemical use.

The domestic demand for ethane (including ethylene) increased 4.3% to 124.6 million barrels in 1974. Virtually all ethane is used for petrochemical feedstocks. According to the U.S. International Trade Commission, 1974 production of ethylene increased to an alltime high of 23.5 billion pounds. This compares with 5.9 billion pounds in 1960, 18.5 billion pounds in 1971, and 22.4 billion pounds in 1973.

PRODUCTIVE CAPACITY

According to AGA, estimated productive capacity at yearend 1974 was 2.4 million barrels per day, an increase of 5,000 barrels per day or 0.2% during the year. Each of the traditional leading producing States declined in productive capacity during the year except Oklahoma, which experienced a 5,000-barrel-per-day increase. Louisiana had the greatest decrease, losing 85,000 barrels per day (11% of its capacity), followed by Kansas, 14,000 barrels per day (10%); Texas, 13,000 barrels per day (1.2%); and New Mexico, 4,000 barrels per day (4%). For the first time, Florida showed a significant productive capacity of 116,000 barrels per day.

As NGL production is a function of natural gas production and processing, productive capacity is dependent upon rates of gas production from crude oil and natural gas reservoirs. AGA has defined productive capacity of NGL as the amount of hydrocarbon liquids that would be produced coincident with the estimated productive capacity of natural gas based on unit recoveries at normal producing rates. Such estimated capacities are not limited by lack of capacity of processing plants or other surface facilities, and it is emphasized that adequate facilities would be required to effect the recovery of liquids from the natural gas produced at these rates.

It should also be recognized that such facilities cannot be enlarged quickly. Therefore, the estimated NGL capacities relate to increased production of gas from oil and gas wells operating at their productive capacities, are theoretical and may not be realized in the event of an emergency.[4]

STOCKS

Stocks of NGL reached a record high of 133.2 million barrels on September 30, 1974. There were no critical drawdowns on propane stocks during the year. The lowest level for propane stocks occurred on February 28, 1974, which totaled 52.1 million barrels or 54 days of domestic propane demand. This compares with February 1973 stocks of propane which totaled 31.7 million barrels and represented only 24 days of domestic propane demand. Propane demand in February 1974 was a little more than 25% below the February 1973 demand. This building of stocks to secure levels reflects the generally warmer than usual winter weather that occurred across the nation.

Total NGL stocks at both refineries and plants and bulk terminals at yearend 1974 totaled 114.3 million barrels, or 15.4 million barrels more than at the yearend of 1973. A little over 75% of this total was in underground storage. NGL stocks at refineries amounted to 5.9 million barrels, an increase of 1.1 million barrels from stocks at yearend 1973, whereas stocks at plants and terminals totaled 108.4 million barrels or 14.3 million barrels more than at yearend 1973. By type of liquid the major yearend stock increases at plants and terminals were: Butane, up 5.4 million barrels; propane, up 5.0 million barrels; and isobutane, up 3.4 million barrels. Ethane stocks had a slight reduction of 0.5 million barrels.

As domestic propane production declines, the gap between supply and demand will be made up by increasing imports. In preparation for this, more and more companies within the LPG industry are expanding their storage facilities. For example, Petrolane Inc. completed construction of a refrigerated LPG storage terminal on the west coast, the largest in the United States.

PRICES AND VALUE

The average unit value of NGL was $5.01 per barrel, up significantly from the 1973 level of $2.93 per barrel. The sharpest increase occurred in natural gasoline and isopentane, as indicated in table 5. LPG and ethane total value accounted for 64.1% of the NGL total value. Although the volume of LPG and ethane increased less than 1%, the aggregate value of production rose some 66.7% resulting from a 66.2% increase in the unit value of LPG and ethane.

Most of this price increase occurred in LPG since there is no spot market for ethane. Also, sales of ethane are usually made under long-term contracts and therefore ethane prices do not fluctuate as widely and frequently as propane and butane prices. Propane prices for example, rose sharply during the year; the average price paid for propane in Baton Rouge, La., was 16.06 cents per gallon compared with the 1973 average price of 9.13 cents per gallon, an increase of 76%. Table 17 indicates the comparison of the monthly prices paid for propane at various locations throughout the United States.

FOREIGN TRADE

Total imports of plant condensate and LPG in 1974 amounted to 77.1 million barrels. This represents a decrease of 8.2 million barrels or 9.6% from LPG and plant condensate imports in 1973. The decline in imports reflected the general slackening in demand for LPG. Despite this reduction in imports, LPG and plant condensate imports were, on a volume basis, the third most important item of liquid hydrocarbon product imports, ranking behind residual and distillate fuel oils.

The number of countries from which the United States imported LPG dropped from 22 to 14 in 1974. Canada and Venezuela continued to lead all other countries supplying 81% and 16% respectively of total United States LPG and plant condensate imports.

Canada supplied nearly all of the plant condensate imports (98%) although these imports declined by 15% from the 1973 level.

PAD district II continued as the leading importer among the five districts, accounting for 43% of LPG imports. Imports into district I declined by 2.6 million barrels or 30% from the 1973 level.

Mexico continued as the leading importer, receiving over 98% of all LPG exported from the United States. Total LPG exports amounted to about 9 million barrels, a decline of 9.0% from 1973. However, value of LPG exports rose 62% to $92.7 million reflecting the increased price of LPG.

As indicated in table 19, Japan's total imports of propane from the United States in 1974 declined to 1,003 barrels from the 1973 levels of 401,000 barrels. This decrease reflects a shift in the purchase pattern by Japan to other propane exporting countries.

The breakdown of exports between the various products were as follows: Butane 1.5%, propane 25.9%, and butane-propane mixtures 72.6%.

WORLD REVIEW

The United States and Canada dominated world natural gas plant liquids output. Their combined production accounted for 72% of the total world production. In the Middle East, NGL production from the three major producers of associated gas, Iran, Kuwait, and Saudi Arabia, amounted to 71.8 million barrels or 7% of the total. Of these countries, as indicated in table 20, Saudi Arabia showed the largest increase in production.

In Algeria construction began on a plant to produce 450,000 tons per year of butane and propane, with allowances for future expansion to 750,000 tons per year. This plant is to be constructed by the State-owned petroleum company, Société Nationale pour la Recherche, la Production, le Transport, la Transformation, et la Commercialisation des Hydrocarbures (SONATRACH). Construction began in Argentina on a natural gas processing plant to produce 61,500 tons per year of propane and butane.

The Canadian Government approved two projects, one a major ethylene plant and the other a dual pipeline system, to transport ethane and propane to the United States and throughout Canada. An ethane plant will be built at Fort Saskatchewan by Dow Chemical of Canada Ltd. Dome Petroleum Ltd. will build a twin pipeline system from Fort Saskatchewan to Sarnia, Ontario. One will carry ethylene from Alberta to Sarnia and the other light hydrocarbons, mainly ethane, to a point in Michigan. The hydrocarbons line will then join a new line to Green Springs, Ohio. Initially, Dome will be permitted to export 84 million barrels of ethane between 1976 and 1983 and 17 million barrels of propane between 1978 and 1982. Canada had proved NGL reserves of 1.6 billion barrels at the end of 1974. This represents a 25-million-barrel increase over the 1973 yearend reserve figure and ended 4 consecutive years of decline.

The Government of Dubai entered a joint venture with Sunningdale Oils, Ltd., to construct a gas-processing plant and gathering facilities to extract NGL. In Dubai as in most other Persian Gulf oil-producing States, large volumes of natural gas, being produced in association with the output of petroleum, are currently wasted.

The Hungarian Oil and Gas Trust began construction of a new plant at Szeged, Hungary, for processing natural gas. First stage processing capacity is 3.75 million cubic feet of gas per day.

Atlantic Richfield Co. finalized plans for the construction of a 375,000-barrel-capacity, prestressed concrete LPG storage barge. This barge, the first ever constructed for refrigeration and storage of LPG, is a part of the world's first totally offshore facility for the recovery, storage, and loading of NGL. This facility is currently being built in the Java Sea offshore Indonesia.

In Saudi Arabia the Arabian American Oil Company announced that its production of NGL rose by some 42% during 1974 to an average of about 138,000 barrels per day.

Texas Eastern Transmission Corp. and a Northern Natural Gas Co. subsidiary, UPG Inc., bought 143 acres on the Houston Ship Channel for a major terminal for gas liquids imports. The project would involve a 14-mile pipeline to Texas Eastern's Mont Belvieu, Tex., underground-storage terminal. This action is in anticipation of future increased imports required to close the gap between domestic demand and domestic supply of NGL.

TECHNOLOGY

New cryogenic technology for extracting higher percentages of the ethane from natural gas has been developed. Extraction of ethane in the range of 70% to 80% of total content in the gas was generally uneconomical until the development of this new cryogenic technique. Thus, industry now has the ability to add large new increments of ethane from an essentially static natural gas supply.

The technique employs turbines through which high-pressure gas is expanded, resulting in very low temperatures (about −150°F). Ethane and heavier components of the gas are liquefied at the low temperatures, allowing their separation from the gas.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, others, including most notably Hungary, the People's Republic of China, and Romania, may also produce natural gas plant liquids, but information is inadequate to make reliable estimates of output levels. Every effort has been made to include in this table only those natural gas liquids produced by natural gas processing plants, and to exclude natural gas liquids obtained from field treatment facilities including wellhead separators, because the latter are normally blended with crude oil and thus are included in statistics on crude oil output. In some cases, however, sources do not clearly specify whether data presented represent only output of natural gas processing plants, or if they include field output. Thus, some of the country figures in this table may include field condensate. Where this appears to be the case, the country has been so footnoted, but it may also be true of other countries.

[3] Total of listed figures only, and as such represents an incomplete total, due to the fact that in the case of some countries, only the total butane and propane or only the total of natural gas liquids is reported in sources, and available information is inadequate to estimate the distribution of these totals by individual type. Summation of totals of propane and butane thus does not equal the reported subtotal, nor does the summation of this subtotal and natural gasoline and other equal the reported natural gas plant liquid total.

Nickel

By John D. Corrick [1]

Domestic nickel consumption in 1974 exceeded the high level reached in 1973 and resulted in a tight supply situation that lasted through most of 1974. The limited availability of nickel resulted from record consumption and a substantial increase in consumer stocks. The supply situation was compounded by delays, up to 6 months, in the scheduled startup of Marinduque Mining & Industrial Corp.'s mine and smelter in the Philippines, Freeport Queensland Nickel Inc.'s mine and treatment plant in Australia, Amax Nickel Divisions' rehabilitated refinery in Louisiana, and production from the mine and smelter located in Botswana. Data collected by the Bureau of Mines indicated that the level of activity in the domestic nickel industry in 1974 was little changed from that in 1973. Domestic nickel consumption in 1974 exceeded the record consumption reported in 1973 by 5% and amounted to 208,000 tons. Ferronickel increased its share of the domestic nickel market in 1974 at the expense of pure nickel, but nickel oxide retained its 1973 market share. The pattern of nickel consumption in 1974 changed very little from that of recent years with approximately 47% consumed in steels, 21% in other nickel and nickel alloys, and 13% in electroplating.

Changes that occurred in the U.S. supply base for nickel in 1973 became more pronounced in 1974. Imports of nickel from the U.S.S.R. continued to increase and were nearly three times those of 1973. Next to Canada, the principal U.S. supply sources for nickel were New Caledonia, the Dominican Republic, Norway, the United Kingdom, and the U.S.S.R. The United States imported a record 220,655 tons of nickel in 1974.

The prices of various primary forms of nickel showed considerable upward movement during 1974. Yearend prices for the major primary forms were as follows: Electrolytic, $2.01 per pound; FN3, FN4, and FNC, $2.02, $1.98, and $2 per pound, respectively; and domestically produced ferronickel, $1.97 per pound.

DOMESTIC PRODUCTION

The Hanna Mining Co. at Riddle, Oreg., was the sole U.S. producer of primary nickel in 1974. Byproduct nickel salts and metal were produced at copper and other metal refineries; part of the byproduct nickel originated from scrap. Amax Nickel Division of AMAX, Inc. began production of nickel late in 1974 at its rehabilitated nickel-copper refinery at Port Nickel, La. The first 40-ton shipment of nickel-copper matte produced in Botswana was shipped to Port Nickel in March. The principal products will be nickel briquets, copper, and cobalt. Interest in the possible development of copper-nickel deposits in northeastern Minnesota remained high throughout 1974. Numerous hearings were held and environmental reports produced dealing with controversies over developing the deposits. The International Nickel Co. of Canada, Ltd. (INCO), asked for and received permission from the U.S. Forest Service to mine 10,000 tons of copper-nickel ore from Federal lands southeast of Ely, Minn. The ore was to be shipped to INCO's Canadian facilities for testing. Near yearend AMAX Exploration, Inc., was seeking approval to dig a 1,700-foot-deep test shaft near Babbitt, Minn. A task force formed by the Minnesota Environmental Quality Council (EQC) began a study of the potential impact of copper-nickel mining in Minnesota. The interagency task force estimated that 3 years would be required to complete the study.

CONSUMPTION AND USES

The domestic nickel industry in 1974 continued to consume a proportionately greater amount of ferronickel than in previous years. In 1974, ferronickel accounted to 22% of the total nickel consumed compared with 18% in 1973 and 14% in 1972. Most of the ferronickel was consumed in stainless and alloy steels. Pure nickel accounted for 59% of the total nickel consumed in 1974 compared with 62% in 1973 and 69% in 1972. Principal consumption of pure nickel occurred in the production of nickel wrought products and nickel alloys, electroplating, stainless steel, and superalloys. The pattern of nickel consumption in 1974 was as follows: 35% in stainless and heat resisting steel, 21% in other nickel and nickel alloys, 13% in electroplating, 11% in alloy steel, and 6% in superalloys.

Consumption of nickel in 1974 was spurred on by strong demand for nickel-bearing alloys from chemical-processing and energy-related industries and turbine engine manufacturers. Turbine engines have found increased usage in marine applications, standby electrical-power-generation equipment, and pipeline transmission pumps. Reportedly, usage of nickel-bearing stainless steel in automobiles increased in 1974, with the single largest application being in wheel covers. Other new and innovative uses of stainless steel in automobiles were in valves and levers that make up the early fuel evapcration (EFE) system being used on General Motors Corp. cars. Also more extensive use was made of stainless steelclad brakeline tubing during 1974.

Other [1]	1,363	1,250	10	226
Total reported by companies canvassed and estimated	53,312	49,585	1,854	6,668

W Withheld to avoid disclosing individual confidential data; included with other uses.
[1] Includes companies that consume nickel bearing scrap in more than one end use category.

PRICES

The producers' price for electrolytic nickel showed considerable upward movement during 1974. Prices increased from $1.53 per pound to $1.62 per pound on January 4. Falconbridge Nickel Mines, Ltd. (Falco) raised the price to $1.85 per pound on May 16; INCO followed on June 28. Falco again raised the price to $2.05 per pound on December 1; INCO responded by raising the price to $2.01 per pound on December 20. Domestically produced ferronickel was increased on January 4 to $1.53 per pound of contained nickel and again on May 16 to $1.81 and finally on December 27 to $1.97. Price increases for domestically produced ferronickel reflected increased costs in labor, materials, and supplies according to a Hanna Mining Company spokesman. The price of foreign-produced ferronickel was increased several times during 1974. The new prices effective October 18 were as follows: FN4, $1.98 per pound nickel content; FN3, $2.02 per pound nickel content; and FNC, $2 per pound nickel content.

FOREIGN TRADE

U.S. exports of nickel, nickel alloys, and catalysts were 53% more than those of 1973. The quantity of exported nickel waste and scrap remained virtually unchanged from that of 1973, but the value of 1974 exported scrap increased by 34% over that of 1973.

Record quantities of nickel were imported in 1974, and exceeded 1973 imports by 16%. Canada again dominated as the principal supplier in 1974 and accounted for 58% of the total nickel imported for consumption. Other major countries supplying the United States with nickel, in decreasing order of magnitude, were the Dominican Republic, New Caledonia, Norway, the United Kingdom, and the U.S.S.R. These countries in combination with Canada accounted for 92% of U.S. nickel imports in 1974. Imports of ferronickel (gross weight) continued to gain a larger portion of the total nickel imports and accounted for 33.7% of the total in 1974 compared with 32.7% in 1973.

[1] Ore: 1973, Australia 113, Colombia 8,094, France less than 1 short ton; 1974 French Pacific Islands 62.

[2] Nickel-containing materials in slurry, or any form derived from ore by chemical, physical, or any other means, and requiring further processing to recover nickel or other metals.

[3] Less than ½ unit.

WORLD REVIEW

Australia.—Late in 1974, the Australian Government disclosed new guidelines for foreign equity participation as it relates to control of the mining industry in Australia. The guideline's basic aim was to insure that the mineral resources of Australia were developed and that maximum benefits accrued to the Australian people. Thus, all mining enterprises must conform with the national interest. A major objective will be to promote Australian equity in and control of its resources and industries. The Government desires maximum Australian ownership of all mining enterprises engaged in exploration, development, or processing. The Government also prefers both public and private participation in mining operations. The Australian Minister for Minerals and Energy requested that he be informed of all major mineral proposals, whether by Australian or foreign enterprises, early in the development stages.[2]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Insofar as possible, this table represents mine production of nickel; where data relate to some more highly processed form, the figures given have been used in lieu of unreported actual mine output to provide some indication of the magnitude of mine output, and are so noted, parenthetically, following the country name.

[2] In addition to the countries listed, East Germany also produces nickel from mines, but output is not reported quantitatively and available information is inadequate for formulation of estimates of output levels.

[3] Refined nickel and nickel content of oxides and salts produced, plus recoverable nickel in exported mattes and speiss.

[4] Includes a small amount of cobalt not reported separately.

[5] Nickel-cobalt content of metallurgical plant products, plus recoverable nickel-cobalt in exported ores.

Byproduct of metal refinery	2,505	958	873
Recovery from domestic ore	13,226	12,937	13,220
Total	[r] 654,032	721,348	798,118

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Refined nickel plus nickel content of ferronickel produced from concentrates unless otherwise specified.

[2] In addition to the countries listed, East Germany and North Korea are believed to produce metallic nickel and/or ferronickel, but information is inadequate for formulation of reliable estimates of output levels.

[3] Nickel content of nickel-copper-cobalt matte produced and shipped to the United States for refining. Refined nickel recovered from this matte is not included with U.S. production.

[4] Includes nickel content of nickel oxide and nickel fonte in addition to metallic nickel and ferronickel.

[5] Nickel content of ferronickel only. (No refined nickel is produced.)

[6] Includes electrolytic nickel as follows in short tons: 1972—18,189; 1973—23,249; 1974—22,969; the difference between these figures and the listed total is the nickel content of ferronickel, nickel oxide and nickel fonte.

[7] Nickel-cobalt content of ferronickel and matte.

[8] Electrolytic nickel from sources specified only; excludes electrolytic nickel produced from imported matte (see footnote 3) as well as nickel content of ferronickel and fonte.

Western Mining Corp., Ltd., the world's fourth largest nickel producer among market economy countries, continued its expansion programs during 1974. During the year, production at Kambalda was increased, and in September, production began at the Windarra mine, which Western Mining jointly owns with Poseidon Ltd. Planned capacity at Windarra is expected to be 14,000 tons per year of contained nickel. Expansion of the Kalgoorlie nickel smelter was at an advanced stage late in 1974. The smelter capacity was to be expanded to about 38,500 tons of nickel per year in matte. Western Mining also was expanding the capacity of the Kwinana refinery to 33,000 tons per year of refined nickel. The expansion entailed construction of additional ammonia and hydrogen plants and installation of another autoclave and supporting equipment. Additional exploration at Kambalda and in the Paris-St. Ives area near Lake Lefroy resulted in the discovery of additional nickel mineralization. New reserve estimates for this area in Western Australia were 24.6 million tons of ore averaging 3.22% nickel.

Selcast Exploration Ltd. became the fourth company in Australia to develop nickel deposits. Spokesmen for the company estimated reserves at 880,000 tons of ore averaging 2.4% nickel near Spargoville. Selcast planned to sell its entire output of nickel concentrate to Western Mining. Deliveries were expected to start early in 1975 and continue until mid-1978. Purchase of the concentrate from Selcast was to coincide with production startup at the Poseidon-Western Mining Windarra nickel mine in Western Australia. The two operations were expected to boost Western Mining's nickel output approximately 50%.

The Greenvale nickeliferous laterite project in Queensland was to be completed by the end of December 1974, and shipments were expected to begin in January 1975 on a limited basis. Early in 1974, estimated direct operating costs for producing nickel and cobalt were raised from the original 50 cents per pound of nickel-cobalt to 65 cents per pound of nickel-cobalt. Company officials attributed the increase in cost to revaluation of the Australian dollar, a rapid rate of inflation in Australia, and drastic increases in fuel oil prices. Reportedly, 40,000 tons per year of Bunker C fuel oil will be consumed in processing the ore. After the ore has been crushed and ground, it will be mixed with 4% heavy fuel oil by weight. This mixture will be fired in reduction furnaces where the nickel and cobalt will be reduced to a metallic state. The reduced ore will be slurried in a solution containing ammonia and ammonium carbonate, which will dissolve the nickel and cobalt. After iron is precipitated from the solution, cobalt and nickel will be stripped by hydrogen sulfide to produce a mixed sulfide product. Nickel will be removed by steam and formed into a nickel carbonate cake. Calcining the carbonate cake with fuel oil will produce an oxide product containing 70% nickel. Treatment of the oxide in a reduction furnace with hydrogen will produce an upgraded oxide product containing 90% nickel. This product will be pressed into briquets and sintered in a nitrogen atmosphere to produce commercial-grade nickel oxide 90. At yearend, proven reserves at Greenvale were estimated at 44 million tons averaging 1.57% nickel and 0.12% cobalt.

Late in November, the Government of Western Australia signed an agreement with Western Selcast Pty. Ltd. and Mount Isa Mines, Ltd. for development of the Agnew nickel deposit located approximately 400 miles northeast of Perth. Western Selcast will have 60% interest and Mount Isa 40% in the joint venture to be managed by the newly formed Agnew Mining Co. Pty. Ltd. The project will require construction of a town to house about 3,000 people, and a mine and associated facilities for producing nickel matte. The agreement specifies that the partners will explore the possibility of establishing a nickel refinery in Western Australia within 10 years. Initially, the smelter will operate at a rate of 20,000 tons per year of nickel matte; the rate will be gradually increased to 30,000 tons per year. An Outokuompu flash smelter was selected because the unit requires only one-half to two-thirds as much fuel oil as do traditional electric smelters. Construction at Agnew was to begin about the middle of 1975, and the first nickel matte is to be produced by the end of 1977. The matte will contain 77% nickel.

Botswana.—Officials of Botswana Roan Selection Trust, Ltd. (BRST), stated that its subsidiary, Bamangwato Concessions, Ltd. (BCL), began mining ore at the end of 1973 and that small shipments of matte had been made from the smelter during 1974. The ore was mined at the Selebi-Pikwe ore bodies with a combined reserve estimated at 35.4 million tons proven and 12.8 million tons probable. BCL's production was delayed because of technical problems in the smelter's spray dryer at the surface treatment plant. The initial production of copper-nickel matte was to be toll refined at Amax Nickel Division's Louisiana refinery persuant to a 15-year refining agreement.

Brazil.—INCO entered into a participation agreement with a West German consortium comprised of Metallgesellschaft AG. of Frankfurt and Exploration und Bergbau GmbH of Düsseldorf to develop lateritic nickel deposits at Barro Alto in the state of Goiás, Brazil. The Brazilian company, Baminco Mineração e Siderúrgia S.A. (BAMINCO), holds rights to the mining concessions at the Barro Alto deposits. The company has conducted geological and metallurgical work since 1970. BAMINCO was to mine a bulk sample of ore and ship it to INCO's Port Colborne, Ontario, Canada, pilot plant for testing in 1974. Under an agreement submitted to the Brazilian Government in December 1972, and approved in May 1973, INCO and the West German group were to have equal interests in the project and in BAMINCO.

Burundi.—Nickel deposits were discovered in Burundi by a United Nations minerals survey team in 1973. Members of the team reported the nickel deposits as being significant. Nevertheless, major problems must be overcome if and when the deposits are proven to be exploitable. Large infrastructure costs would be incurred in developing the deposits, and adequate access to the sea and power sources would be necessary.

Canada.—Canadian nickel production in 1974 was 9% greater than in 1973 and accounted for 36% of total world mine production. Leading producers of nickel in Canada were INCO, Falco, and Sherritt Gordon Mines, Ltd.

INCO mined a total of 22 million tons of ore averaging 1.37% nickel and 0.97% copper compared with 19.7 million tons in 1973 averaging 1.41% nickel and 0.98% copper. The company produced a record high of 510 million pounds of nickel in 1974 compared with 469 million pounds in 1973. INCO initiated a new program in 1973 to expand the output of nickel in Canada and continued it through 1974. Annual production of nickel in 1975 is expected to exceed 520 million pounds. Company officials indicated that increased production in 1974 was due to improved underground operating efficiencies. INCO operated 16 mines during 1974, 13 in Ontario and 3 in Manitoba while maintaining 2 mines in Ontario and 1 in

Manitoba on standby. Production of nickel ore from the Crean Hill mine was resumed in January 1974. Preparatory work at the Clarabelle open pit mine in Sudbury was completed in December 1974; and mining was to resume at a later date. The Copper Cliff nickel refinery completed its first full year of operation in 1974, but did not achieve full capacity owing to problems with preparation of feed material. INCO was attempting to overcome this problem by increasing the capacity of the top-blown rotary converter plant in order to equal the designed 125 million pounds capacity of the carbonyl plant. According to company officials, operation of the 1,250-foot smelter chimney along with technological improvements in the Sudbury operations, have improved air quality in the region. Construction on two waste-water treatment plants in the Sudbury area was begun in 1974; these plants were to be operational in 1975. INCO officials reported proven ore reserves in Canada of 414 million tons at the end of 1974, containing 6.7 million tons of nickel and 4.2 million tons of copper. This compared with 399 million tons at the end of 1973, containing 6.5 million tons of nickel and 4.1 million tons of copper.

Falco mines delivered 4,337,000 tons of nickel ore to treatment plants in 1974 compared with 4,293,000 tons delivered in 1973. Nevertheless, deliveries of refined nickel decreased from 49,704 tons in 1973 to 44,732 tons in 1974. Development of the Lockerby mine continued through 1974. At yearend, the No. 2 shaft had reached the 4,200-foot level. Ore production from Lockerby was expected to reach one-third the rated maximum output in the last quarter of 1975. The ore will be shipped to the Strathcona mill for processing. Enlargement of the Strathcona mill was near completion at yearend. Development of other Falco mines in the Sudbury area continued throughout 1974 with the sinking of additional shafts. Ore production from the Manibridge mine in Manitoba was increased from 136,000 tons in 1973 to 184,000 tons in 1974. Temporary shutdowns of short duration were encountered during 1974 to alleviate temporary peaks in the emission of sulfur dioxide and as a result of coke shortages. Falco began work on a smelter environmental improvement program at Sudbury in 1974. The project, to include a sulfuric acid plant, will cost an estimated $95 million. Falco reached a settlement early in 1974 regarding financial claims on its nickel-iron pellet refinery. The company's total proven and probable ore reserves at the Sudbury and Manibridge operations at the end of 1974 were 90,578,000 tons containing 1,266,000 tons of nickel and 615,000 tons of copper compared with 92,798,000 tons of ore containing 1,271,000 tons of nickel and 632,000 tons of copper at yearend 1973.

Sherritt Gordon, Canada's third-largest producer of nickel, experienced some difficulty with its Lynn Lake nickel-copper-cobalt mine as a result of lagging ore production. According to company officials, principal reasons for reduced output were excess dilution of the ore from some of the open blasthole stopes and a shortage of experienced miners. Giant Mascot Mines, Ltd., which was shipping ore to Sherritt Gordon for refining, reportedly exposed a new zone of mineralization at its Giant Nickel property in British Columbia. The mineralization was exposed when a new road was constructed by a logging company across land on which Giant Mascot owned the mineral rights. At yearend, no indication was given as to the extent of the mineralization.

Sales, deliveries, or production, as reported by the three principal Canadian producers in 1974, were as follows:

Company	Type of operation	Thousand pounds
The International Nickel Co. of Canada, Ltd	Delivery	549,000
Falconbridge Nickel Mines, Ltd	do	89,464
Sherritt Gordon Mines, Ltd	Sales	16,142

After considerable drilling, feasibility and engineering studies, mine planning, and expense (estimated at $10 million), Great Lakes Nickel, Ltd., of Canada and Boliden A.B. of Sweden suspended development of their joint nickel-copper mining venture near Thunder Bay, Ontario. According to company officials, the $38 million project was placed on standby because of cost escalations, high interest rates, and unstable metal prices. Indicated reserves were 106 million tons averaging 0.4% copper and 0.2% nickel. Hollinger Mines, Ltd. continued an exploratory drilling program at its coowned nickel-copper prospect near Timmins, Ontario. Reportedly, test samples averaged 0.23% copper and 0.35% nickel. Other companies associated with this venture were Imperial Oil, Ltd. (Exxon Corp.) with a 42.5% share equal to that of Hollinger; the remaining 15% was equally divided among Dome Mines Ltd., Jorex Ltd., and Driftex Ltd.

Cuba.—The Cuban Government's program to increase production at the Nicaro and Moa Bay nickel operations, and the opening of a new mine (Punta Gorda) and three processing plants in Oriente Province would cost an estimated $350 to $450 million. Of the total investment, $300 to $400 million was earmarked for the new operations. The capacity of each plant would be 33,000 tons per year of nickel contained in nickel oxide sinter pellets. Reportedly, the pellets will contain 77% nickel and 3% cobalt. Government officials reported that feasibility studies and preproject planning for the new mine, water supplies, powerplants, and railway and port facilities have been completed. Construction was to begin by 1976–77 with planned startup of one plant scheduled for late 1978. The remaining two plants would begin operating between 1980 and 1985. Ore grade in the area of the three plant sites was reported to be 1.37% to 1.4% nickel. The ore was to be mined by open pit techniques. Approximately $40 million of the investment was to be spent on the Nicaro operation to modernize equipment and bring production up to the full designed capacity of 23,000 tons. The remaining $10 million was to be spent on the Moa Bay operation to upgrade processing facilities. Reportedly, the capacity at Moa Bay will not be increased.

Cuba uses very little of the total amount of nickel it produces annually. The U.S.S.R. purchases nearly 50% of the output; Czechoslovakia, Romania, France, England, Italy, and Japan take the remainder.

Dominican Republic.—Falconbridge Dominicana C. por A. achieved full designed production capacity in March 1973. Increased fuel oil prices, as reflected in production costs, affected Falconbridge Dominicana's contribution to the company's overall consolidated earnings. The total effect of oil price increases was partially offset by operational economies and plant modifications. Price increases for ferronickel that were announced during 1974 were expected to yield a limited benefit to company profits for the year 1974. Although deliveries of ferronickel through the first 6 months of 1974 were 18% greater than for a similar period of 1973, company officials reported that deliveries in the second half would be less in order to restore producer ferronickel inventories to more normal levels. Falconbridge Dominicana was successful in negotiating a 3-year labor contract in November 1973, which provided the employees with increased salaries and benefits.

Guatemala.—Good progress was reported on the development of nickel deposits located near Lake Izabal in eastern Guatemala. Site preparation for the plant and town had been underway for some time and was nearing completion. The development company known as Exploraciones y Explotaciones Mineras Izabal, S.A. (Exmibal), was 80% owned by INCO and 20% by Hanna. Reportedly, provisions were made for the Government of Guatemala, the International Finance Corp., and the Central American Bank for Economic Integration to acquire up to 36% of Exmibal. A peak force of 1,200 people were to be employed during the construction phase and 700 people employed to operate the plant.

India.—Reportedly, the Indian Government gave approval to develop the Sukinda nickel project in the State of Orissa. The nickel lateriate deposit was estimated to contain 65 million tons of ore having an average nickel content of 0.85%. Planned capacity was 4,800 tons of nickel and 200 tons of cobalt per year. Government officials reported that India's demand for nickel will continue to rise from the present level of 4,800 tons to about 12,400 tons per year by 1978–79. A byproduct of the plant will be 17,000 tons of ammonium sulfate per year, undoubtedly to be used as fertilizer.

Indonesia.—P. T. International Nickel Indonesia, a wholly-owned subsidiary of INCO, in combination with six Japanese partners was proceeding with the development of a mine and processing plant in Indonesia. The facilities will produce a nickel matte containing 75% nickel from lateritic ores located near Soroaka, in central Sulawesi. Plant output is committed to three of the Japanese partners for 15 years. Improvement of the pyrometallurgical process to which the ores will be subjected has permitted an upward revision of output projections from 30 to 35 million pounds of nickel annually. Development of the project will require a peak employment of 1,300 people in 1975, and will stabilize at approximately 1,100 when the plant and mine are in production. The company continued to explore the possiblity of expanding production to 90 or 100 million pounds of nickel annually at a later date. Also being considered by the company was an option to use the hydroelectric potential of the area rather than relying on petroleum as the project's energy source. Reportedly, INCO held 18% of the original 6.6-million-hectare contract area and was continuing its systematic exploration program. Dravo Corp. holds the engineering and construction contract for the complex. Dravo's contract included construction of port facilities (already begun), supporting utilities, a town site, roads, a cross-country pipeline, and the plant itself, which is to be equipped with a top-blown rotary converter. Davy Ashmore International of the United Kingdom was to supply the top-blown rotary converter for the plant. At yearend, the project was still scheduled for startup in 1976.

P. N. Aneka Tambang (ANEKA), a state-owned mining company, was the only producer of nickel in Indonesia during 1974. The company exported ores to Japan from its Pomelaa mine located near Kendari, in south Sulawesi. ANEKA's overall development program called for the production of ferronickel at Pomelaa, as a means of utilizing low-grade ores remaining at the site, when the exportable grades of ores become depleted. Construction of a $32 million, Japanese-financed, smelter was well underway at midyear; the company expected to be in production by early 1976. ANEKA conducted geologic mapping and test sampling of large low-grade nickel deposits in Southeast Kalimantan during much of 1974.

Engineering, design, and procurement activities have been brought to the point where infrastructure and facility construction can readily be undertaken if P. T. Pacific Nikkel Indonesia decides to proceed with the development of its giant Gag Island nickel project on Irian Barat. However, the partners in the consortium have adopted a holding position pending the resolution of fuel oil prices, supply problems and clarification of the financial terms that would be attainable for the project. At midyear, engineering and procurement activities were temporarily suspended. Nevertheless, a task force was working on construction and site preparation on Gag Island.

The Indonesian Nickel Development Co. (INDENCO), a partnership of four Japanese smelters and three trading firms, had completed initial reconaissance of its contract area in Halmahera and the surrounding islands. At midyear, INDENCO was conducting studies to establish a logistics base for its operation. Reportedly, the company had indications of relatively high-grade lateritic nickel ore on the Islands of Gebe and Obi.

Japan.—Japan's nearly total dependence on four countries for 90% of its nickel supply (New Caledonia, 47.1%; Canada, 18.7%; Australia, 12.4%; and Indonesia, 11.1%) was the motivating force behind a desire for stockpiling 8,800 tons of nickel. Reportedly, this quantity would give the country a 3-month supply. Other moves by Japanese firms to secure long-term supplies of nickel for their industry was evidenced by the fact that Japanese companies entered into several consortia to develop and process manganese nodules found in the Pacific Ocean. Manganese nodules are estimated to contain 1.6% nickel and other associated metals.

By mid-1975, Japan's two producers of nickel, Sumitomo Nickel Mining Co., Ltd., and Shimura Kako Co., will be joined by a third company, Nippon Mining Co., Ltd. Nippon currently has a refinery under construction for producing nickel and cobalt.

Japanese nickel smelter operators planned to hold talks with New Caledonia nickel ore shippers late in 1974 in an attempt to obtain a reduction or deferral of nickel ore shipments to Japan. The reason given for reducing shipments was a declining demand for nickel. In another move to ease what appeared to be a nickel oversupply, the Japanese Ministry of Trade and Industry (MITI) authorized increased exports of nickel ingot for the second half of the fiscal year (October to March). Reportedly, Japan was committed to import about 15,000 tons of nickel and 9,500 tons of ferronickel in addition to ores and matte in 1974. Approximately one-third of the 15,000 tons of nickel imported was to come from the U.S.S.R. under a long-term contract. Most of the remainder was shipped by INCO to Mitsui & Co., Nissho-Iwai, and Sumitomo, the rest was shipped by Falco to Mitsubishi Corp.

Japanese companies were active in numerous nickel developments, principal among these were the development of the Rio Tuba mine in the Philippines, the development of Australia's Greenvale nickel mine, the development of nickel mines in Indonesia, and sales contracts to buy nickel-cobalt sulfide from the Marinduque mine and smelter, which began producing nickel in the Philippines at yearend.

New Caledonia.—Production of nickel ore in New Caledonia in 1974 was 19% greater than that produced in 1973. Nickel smelter production increased nearly 18% in 1974 over that of 1973. Ferronickel production increased 36%, but matte production decreased 12% below that of 1973. Exports of nickel ore to Japan in 1974 increased by 19% when compared with exports in 1973. Next to France, the United States was the leading recipient of ferronickel and matte, followed in decreasing order by Japan, Canada, Finland, and Australia.

The major nickel producer, Société le Nickel (SLN), on New Caledonia concluded several major deals in 1974 that should affect nickel production on the island for many years to come. Early in 1974, SLN sought and obtained an agreement from Kaiser Aluminum & Chemical Corp. to purchase Kaiser's 50% interest in the New Caledonian Nickel Co., thus giving SLN full ownership. According to company officials, the settlement would permit SLN to reinforce its position in world nickel market, while Kaiser Aluminum could concentrate its effort on activities outside the nickel industry. A second major event occurred in March 1974 when the management of SLN announced an agreement in principal with Société Nationale des Pétroles d'Aquitaine (SNPA) to form a joint firm to handle SLN's mining and industrial assets in New Caledonia and France. Under the proposed plan, SLN would be reorganized into a holding company under the name I-Metal. Stockholders also approved the creation of a special nickel subsidiary, Société Metallurgique le Nickel. SNPA's agreement to take a 50% share in I-Metal's newly created subsidiary would depend on the Government's forthcoming tax proposal for New Caledonian nickel processors. Reportedly, SNPA made the first installment of about $20 million to the nickel subsidiary, Société Metallurgique le Nickel. According to SNPA company officials, the decision to join I-Metal would not involve any change in the company's prior decision to join with Freeport Minerals Co. in developing the Goro deposit on New Caledonia. The third major event that occurred during 1974 was the acquisition of approximately 10% of the common stock of SLN by Amax Inc. The stock acquisition by Amax made the company the second largest shareholder, after the Rothchild group's holdings of approximately 26%. According to a company official, Amax planned to purchase material from SLN for feed to its newly refinery at Port Nickel, La.

Compagnie Française d'Entreprises Mínières Métallurgiques et d'Investissements (COFREMMI), a wholly owned subsidiary of Patino N.V., obtained a "go ahead" from the French Government to establish a nickel mining and metallurgical project in northern New Caledonia. COFREMMI was to develop ore deposits in the Tiebaghi and Poum areas of New Caledonia. Proven reserves were 13 million tons of ore containing 3% nickel plus cobalt in garnierite and 17 million tons of 1% nickel plus cobalt in laterite in the Tiebaghi deposits and 35 million tons of 3.2% nickel plus cobalt in garnierite and 41 million tons of 1.34% nickel plus cobalt in laterite at Poum. Company plans called for mining the garnierite first. Société Mètallurgique de Nickel Patino Péchiney Gränges (SOMMONI), a wholly owned subsidiary of COFREMMI, was to build a ferronickel plant and produce 40 million pounds of nickel in ferronickel (35% nickel content) per year. The output may be increased to 80 million pounds per year at a later date. Work on the plant site began in December 1973 and was to be intensified in order to achieve production by the middle of 1976. Société Française d'Electrometallurgie (SOFREM), a subsidiary of Péchiney Ugine Kuhlmann, was to provide technical assistance during the first 15 years of operation. SOFREM had developed and patented an electric furnace process for treating New Caledonian ores and had completed a 12-month pilot plant test. The company was to conduct an additional 6 months of trials with a 5-megawatt semicommercial-size plant. The semicommercial plant was to be used by SOFREM for training personnel who ultimately would operate the smelter in New Caledonia.

At yearend, the French Government still had not made a decision regarding changes to New Caledonia's tax structure. Nevertheless, a decision regarding New Caledonian taxes was expected early in 1975.

Philippines.—Reportedly, Marinduque Mining & Industrial Corp.'s new nickel project on Nonoc Island in the Philippines was producing nickel for sale at yearend. According to an official of Philip Brothers, the sales agent for Marinduque, the 1975 production was practically sold out. The nickel was sold to consumers in Sweden, West Germany, the United States, the United Kingdom, France, and Austria. Major sales were made to the stainless steel and high-temperature-alloy industries. Plant capacity was rated at 75 million pounds of nickel briquets and powder, of which 8 million pounds was to be in the form of a nickel and cobalt concentrate.

Atlas Consolidated Mining & Development Corp. postponed indefinitely the development of its nickel refinery project on Palawan Island. According to company officials, the principal reason for postponing the project was the enormous increases in fuel oil costs. Tests were conducted during the year to see if coal could be used in place of fuel oil as a reductant in treating the ore.

Saturn Minerals Inc. proceeded with preliminary work for development of nickel deposits in northern Leyte. The company requested that the Philippine Bureau of Mines send a team of geologists and mining engineers to evaluate the reported 5.5 million tons of sulfide nickel ores blocked out by five drill holes. Saturn had contracted Konsulta Philippines to make a feasibility study of the project.

Rio Tuba Nickel Mining Corp. signed an agreement to supply 386,000 tons of nickel ore in 1976 and 550,000 tons during each of the succeeding 9 years to four Japanese nickel smelters. The ore would be mined from Rio Tuba's laterite nickel deposits on Palawan Island. The Japanese companies involved were Sumitomo Metal Mining Co., Nippon Mining Co., Nippon Yakin Kogyo Co., and Shimura Kako Co.

Southern Rhodesia.—Johannesburg Consolidated Investment Co. Ltd. expected to begin trial milling at its Shangani nickel mine complex by the middle of 1976. At midyear, access roads and a rail line to the main railhead had been built and surface building construction was underway. The complex was to be composed of a large concentrator, a crushing and screening plant, waterworks, and a pipeline from the Shangani Dam. Mining was to start with an open pit and later continue with a deep-level shaft and conventional underground mine. Reportedly, milling capacity would be 83,000 tons per month. Shangam ore reserves were estimated at 16 million tons. Exploration work being conducted during 1974 at nearby Damba may prove larger deposits. Trojan Nickel Mine Ltd., a wholly owned subsidiary of Rhodesian Nickel Corp. (Rhonickel), acquired nine blocks of claims to the Epoch property in the Filabusi District. Drilling indicated a potential of 2.5 million tons of ore grading 0.75% nickel. Preliminary plans call for the development of a mine shaft and plant to produce nickel concentrate. Reportedly, the Epoch concentrates would be treated along with concentrates from the Shangani mine at Rhonickel's refinery at Bindura.

U.S.S.R.—Late in 1974,, the U.S.S.R. signed a contract with Finland for the delivery of copper and nickel smelting equipment to Norilsk, Siberia. The plants were based on the Outokumpu flash-smelting process and were to be delivered in 1976–77. Outokumpu Oy was to handle the engineering and design automation of the smelters, Rauma-Repola Oy was responsible for the flash-smelting furnaces, concentrate drying equipment, and sulfur-recovery systems; and A. Ahlstrom Oy would supply the boilers and gas purification equipment for the overall process. Reportedly, plant capacities were to be 550,000 tons per year of nickel concentrate and 650,000 tons per year of copper concentrate.

Yugoslavia.—Approximately $300 million was to be invested in the development of a nickel mine and ferronickel plant at Kavadarci, Macedonia. Feni Kombinat was the Yugoslavian company developing the 110 million ton lateritic ore deposit. The mine was to produce 2.2 million tons per year of ore with the nickel plant producing 18,150 tons of nickel and 660,000 tons per year of iron concentrates. The nickel smelter is expected to be operational by 1979.

TECHNOLOGY

Bureau of Mines scientists continued an active research program on nickel recovery from various domestic ores during 1974. The Bureau's research on nickel was being conducted at four metallurgy research centers and dealt with the recovery of nickel from western (Oregon and California) lateritic ores, the Duluth gabbro in Minnesota, and Missouri lead ores. A research project was initiated in July 1974 to investigate the recovery of metals from nodules found on the Blake Plateau in the Atlantic Ocean.

Bureau of Mines scientists reported on the development and application of the waste-plus-waste process for recovering metals from electroplating solutions and other wastes.[3] The method was based on combining various acid and alkaline wastes under controlled conditions so as to neutralize the wastes while precipitating nearly all of the contained metals and cyanides. The process was believed to be suitable for treating major types of electroplating and etching wastes containing cadmium, chromium, copper, nickel, and zinc. Economics of the process were reported to be good while providing a relatively harmless filtrate that met Public Health Service standards for free cyanide content. In a second report,[4] Bureau chemists described their findings regarding stability constants for complexes of diethylenetriamine, 2-aminoethyl sulfide, triethylenetetramine, and 1, 8- diamino-3, 6-dithiaoctane with copper, nickel, zinc, and cadmium. Amine complexes were found to be considerably more stable than the analogous thio complexes. The authors interpreted their findings in terms of possible molecular structure of the complexes.

An international consortium was formed during 1974 to exploit a new process for continuous production of nickel, copper, and lead from sulfide concentrates.[5] The process was co-invented by Drs. Paul E. Queneau of Dartmouth's Thayer School of Engineering and Rheinhardt Schuhmann, Jr. of Purdue University. The Q–S (Queneau-Schuhmann) Process is performed in a single-reaction vessel that is continuously fed oxygen, concentrates, and flux. The net result is a controlled flash oxidation of the sulfide concentrates. Oxygen is fed upward through the molten material by passing it through the refractory lining of the vessel. This marks the first time that such a technique has been applied in nonferrous converting operations. Universal Oil Products Co. (UOP) announced tentative plans to build a $1.6 million pilot plant to demonstrate its new process for extracting nickel from lateritic ores.[6] Spokesman for UOP stated that the process is the first hydrometallurgical one capable of economically processing a variety of lateritic ores. Reportedly, the key to UOP's process is improved ore reduction that permits a recovery of 90% of the nickel in laterite ores.

Scientists at Cabot Corp's Stellite Division discovered a method for producing superalloy ball bearings utilizing powder metallurgy techniques.[7] Powder metallurgy permits the formation of fully dense balls of cobalt-, nickel-, and iron-based superalloys. Bearings thus formed have crush strengths several times greater than cast bearings with a wear life many times greater. Reportedly, material savings of up to 60% are possible through the use of powder metallurgy. A research metallurgist at the NASA Lewis Research Center formulated a new high-strength nickel-based alloy (WAZ–16)that has a higher incipient melting temperature than other nickel-based alloys.[8] The high strength of the alloy is most significant between 1,100° and 1,200° C. It possesses a higher oxidation resistance than other refractory metals. Reportedly, the alloy will have applications in heat-treating furnace fixtures, jet engine components, and power-generating turbine components.

A noteworthy development was announced by scientists at General Electric Co. that involved a possible ceramic substitute for certain types of superalloys.[9] Through the use of special additives, ceramic materials can be sintered to high densities without the use of pressure. The simple procedure permits the formation of complex silicon carbide shapes by extrusion, die pressing, slip casting, and injection molding. Researchers at General Electric foresee the initial use of the ceramic as a structural material for high-temperature gas turbine components that would allow the development of more efficient propulsion and power-generation systems. The material apparently has physical characteristics that would allow it to replace some superalloys.

INCO metallurgists continued investigations into corrosion-resistant alloys at the Francis L. La Que Corrosion Laboratory near Wilmington, N.C., and conducted research on the production and utilization of various nickel alloys at the Paul D. Merica Research Laboratory at Sterling Forest, N.Y. The Merica laboratory recently developed a copper-nickel wire-mesh catalyst for controlling automotive exhaust emissions. The catalyst was being tested by a major automotive parts manufacturer at yearend. If successful, the catalyst would be changed much like an automobile oil filter is changed today. Another recent development by INCO was the formulation of a nickel-magnesium alloy (Incomag 4) used to introduce magnesium into molten iron and steel in producing ductile iron. Inco-Mag 4 is added in the form of heavy pieces and, as such, sinks to the bottom of the furnace. The magnesium is then absorbed by the molten iron and magnesium recovery rates of 80% to 90% are achieved.

Officials of Questor Corp. announced the development of a nickel-based catalyst for controlling automobile emissions that can be used with leaded gasoline. The system would require about 2 pounds of nickel per automobile and cost about $125.[10] The basic nickel alloys are Inconel 601 and a reduction catalyst IN–1013, both supplied by INCO. The catalyst was undergoing tests on various automobiles at yearend.

Reportedly, a potential market for an estimated 30 million pounds of a newly developed alloy IN–838 may exist in uses ranging from marine condensers to power-generating equipment.[11] Company officials stated that the alloy provides superior performance in situations where metal is subjected to high-velocity flows of salt water. IN–838 is a chromium-modified 16% nickel cupronickel alloy.

A large number of patents relating to nickel were issued in 1974, with the main thrust being toward pyrometallurgical and hydrometallurgical extraction procedures. Numerous patents were issued on refining techniques that ranged from chemical precipitation to electrolytic refining. Interest remained high in the recovery of metals, including nickel from seabed nodules, as evidenced by the number of patents issued in 1974. A novel patent was issued to Barringer Research Ltd.[12] covering an aerial geochemical method for exploring for ores of nickel, copper, lead, zinc, silver, and cobalt. The patented method used a device for concentrating airborne particulates from a large volume of air at known localities onto a tape. The particulate matter is later analyzed by spectrophotometry or wet-chemical techniques.

Nitrogen

By William F. Keyes [1]

Production of fixed and elemental (gaseous) nitrogen individually increased 4% over the production in 1973. Exports of fixed nitrogen declined 34%, and imports increased 21%, with the result that the United States was a net importer of this commodity in 1974 for the first time since 1965. Domestic consumption, including 160,000 tons of net imports, rose 3% to just short of 13.0 million tons of fixed nitrogen. Domestic consumption of elemental nitrogen was considered equal to production, as there are no significant stocks, exports, or imports.

One major domestic ammonia plant came onstream in 1974, and plans to construct five others were announced; additional capacity for this basic fixed nitrogen compound was completed at other plants. Total U.S. capacity for the production of anhydrous ammonia was estimated at 17,738,000 tons at yearend 1974.

Table 1.—Salient nitrogen statistics
(Thousand short tons of contained nitrogen)

	1970	1971	1972	1973	1974 [p]
United States:					
Production as ammonia	11,531	12,107	12,651	12,546	13,016
Production as nitrogen gas [1]	5,477	6,087	7,011	8,263	8,575
Exports of nitrogen compounds [2]	1,400	999	1,310	1,506	994
Imports for consumption of nitrogen compounds [2]	942	907	947	951	1,154
Consumption [3]	10,891	11,903	12,333	12,597	12,971
World: Production [2]	42,747	45,357	47,398	[r] 48,500	49,500

[p] Preliminary.

[1] Converted from reported volume (at 70° F and 1 atmosphere pressure) at 27,605 cubic feet per short ton.

[2] Estimated, excludes nitrogen gas.

[3] Includes producers' stock changes in synthetic anhydrous ammonia and coke oven ammonium compounds; excludes nitrogen gas.

DOMESTIC PRODUCTION

Domestic production of fixed nitrogen, as anhydrous ammonia, increased 4% in 1974, reaching 13.0 million tons. Elemental nitrogen production also increased 4%, to 8.6 million tons.

The Fertilizer Institute estimated that almost twice as much ammonia production, or about 340,000 tons, would be lost through curtailment of natural gas supplies in fiscal year 1974-75 as in the preceding year, when curtailments caused a loss of 185,000 to 190,000 tons of ammonia production.[2]

In response to S. Res. 289 of the U.S. Senate, the Federal Power Commission solicited comments from interested persons as to establishing priorities for allocation of natural gas to the fertilizer industry. After consideration, the Commission found that existing procedures were adequate to protect the interests of the fertilizer industries and agriculture-related activities.[3] The Commission further stated that it would continue to entertain petitions for extraordinary relief from curtailment from all natural gas consumers of standing, including fertilizer industries and agriculture-related activities, and grant such relief as might be warranted from the record.

Eighty-nine ammonia plants were operated in the United States during 1974, according to the Tennessee Valley Authority. A list of these plants is given in table 4. One major plant was brought onstream at Enid, Okla., in July by Farmland Industries, Inc.; it had a rated capacity of 1,000 tons per day but attained an output of nearly 1,200 tons per day.[4]

Announced during the year were plans to build five major new ammonia plants, with a total capacity of 6,250 tons per day. W. R. Grace & Co. planned to build a 1,200-ton-per-day plant near Woodward, Okla., at an estimated cost of $70 million.[5] Columbia Nitrogen Corp., Augusta, Ga., a subsidiary of the Dutch firm DSM, was to build a 1,500-ton-per-day plant near its older plant at Augusta.[6] International Minerals & Chemical Corp., with Commercial Solvents Corp., announced plans to build a 1,150-ton-per-day ammonia plant at Sterlington, La., at a cost of $55 million.[7] Agrico Chemical Co. and Farmland Industries, Inc., planned to build a plant with a capacity of 1,250 tons per day at Enid, Okla., adjacent to the recently inaugurated Farmland Industries plant.[8] First Mississippi Corp. also was scheduled to build a 1,150-ton-per-day ammonia plant at Donaldsonville, La.[9] In all, some 12 major ammonia plants were scheduled for completion between 1975 and 1979, including plants announced or started before 1974.

One smaller plant, owned by Agricultural Products Corp. (Beker Industries Inc.) at Soda Springs (Conda), Idaho, was scheduled to enter production at a rate of 300 tons per day in 1974-75, and a 200-ton-per-day plant was also announced, to be built by Tipperary Corp. near Lovington, N. Mex., in addition to Tipperary's smaller plant at the same site, which came onstream in 1974.[10]

The growth in elemental nitrogen production, 4% from 1973 to 1974, was the lowest since a decline was registered in 1968. Growth rates between 10% and 18% were characteristic of the early

CONSUMPTION AND USES

Apparent consumption of contained nitrogen was 13.0 million short tons in 1974. This was calculated, on the basis of preliminary figures, from production, stocks, exports, and imports of ammonia and coke oven compounds and the estimated nitrogen content of exports and imports of nitrogenous materials. This consumption was 3% higher than that in 1973.

It was estimated that 74% of the ammonia used in the United States in 1974 went into fertilizers, 8% into fibers and plastics, 4% into explosives, 3% into animal feeds, and 7% into other uses; losses were estimated at 4%.[12]

Elemental nitrogen had two principal uses: To exclude or purge air from industrial processes, including steelmaking, electronics, chemical manufacture, glassmaking, and others, and as a liquid, to provide low temperatures, through evaporation, in food, shipping, scientific applications, and other processes. These latter cryogenic applications, which are estimated at 18% of total use, were considered to have good growth potential.

PRICES

Prices of all nitrogen compounds approximately doubled during the year. The energy crisis, heavy demand in agriculture, the difficulty of rapidly increasing capacity, and the uncertainty caused by widely varying estimates of future demand all tended to push up prices. Severe inflation in capital and operating costs made it unlikely that prices would, in the future, descend to earlier levels.

FOREIGN TRADE

Exports of contained nitrogen declined from 1,506,000 tons in 1973 to 994,000 tons in 1974. At the same time, imports rose from 951,000 to 1,154,000 tons. The U.S. nitrogen deficit of 160,000 tons in 1974 was the first since 1965. Almost all categories of products showed the same pattern of increased imports and decreased exports, but the pattern was particularly pronounced for anhydrous ammonia.

WORLD REVIEW

It was estimated that worldwide, 126 ammonia plants were announced for construction in the period 1974–80, with an average size of over 1,000 tons per day; this would increase capacity 41% in the period, or 6% per year.[13] As the year progressed, additional plans for construction of ammonia and urea plants were announced. It was uncertain how many of the plants in either category would actually be constructed.

Argentina.—On August 24, representatives of Bolivia and Argentina signed a 16-point Act of Cooperation and Complementation, largely concerned with production of goods from raw materials. One point calls for the construction close to the mutual border of a binational fertilizer plant to produce 1,100 short tons per year each of ammonia and urea.[14]

Bulgaria.—Another ammonia-urea complex will be added to either the Varna or Vratsa fertilizer works to produce about 1,100 short tons per day of ammonia and 2,200 tons per day of urea.[15]

Canada.—Numerous proposals for new petrochemical plants, including ammonia plants, were presented to the Alberta Provincial Government during 1974. Regulations had been amended by the Government to require an industrial permit from the Energy Resources Conservation Board for new plants planning to use natural gas. Emphasis was thus shifting from marketing of resources to conservation.

Three fertilizer projects initiated by companies already operating in Alberta were approved by the Alberta Government and exempted from the permit requirement: (1)Cominco Ltd., for a 400,000-ton-per-year anhydrous ammonia and 480,000-ton-per-year urea plant at Carseland; (2)Western Cooperative Fertilizers Ltd. for 1,200 and 1,500 tons per day of ammonia and urea, respectively, at Medicine Hat; and (3)Sherritt Gordon Mines, for expansion to 1,500 and 1,200 tons per day of ammonia and urea, respectively, at Fort Saskatchewan.[16]

The Deputy Premier of Saskatchewan stated in August that one of the requirements for new ammonia plants was a stepped-up involvement in exploring for and developing new gasfields. Of the 30 proposals for ammonia plants presented in 1973 and 1974, he believed a maximum of 8 plants would result.

Chile.—Sociedad Química y Minera de Chile (SOQUIMICH), Chile's State-owned nitrate corporation, began plans in 1974 for a $35 million expansion program in view of the rise in world nitrate prices brought on by petroleum price increases. Production is expected to rise from 815,000 short tons of all nitrates in 1974 to 935,000 tons in 1975 and 1,045,000 tons in 1976.[17]

Colombia.—Tentative plans for two ammonia plants, each of 100,000-ton-per-year capacity, near the Guajira gasfield were under study; the project would be a joint venture of Texaco and the Empresa Colombiana de Petróleos (ECOPETROL).[18]

Ecuador.—An ammonia-urea plant is high on the list of Government priorities. A minimum production of 66,000 short tons of ammonia is contemplated, based on natural gas deposits in the Gulf of Guayaquil. The plant would most likely be located in the Puerto Bolivar-Machala area.[19]

Egypt.—A protocol signed by Egypt and Iran called for the financing by Iran of a 330,000-ton-per-year ammonia plant in Egypt based on local natural gas. The plant is part of a $1 billion economic cooperation agreement between the two countries.[20]

Germany, East.—A 1,500-ton-per-day, U.S.-designed ammonia plant was brought into production in Piesteritz. A second 1,500-ton plant was under construction at the same location under a contract let by VEB Industrieanlagen Import, an agency of the East German Government.[21]

India.—At the end of 1974 around 15 fertilizer plants were under construction in India, but completion of nearly all had been delayed. Most of these included both ammonia and urea plants. Total output of final product, largely urea, is estimated to be 4.6 million tons when the last plant is commissioned about 1978. The plants will use naphtha, natural gas, coal, and fuel oil as feedstocks.[22]

Indonesia.—A team from the Tennessee Valley Authority completed a report on the potential for the nitrogen fertilizer industry in Indonesia. The report contained hard data confirming a preliminary assessment of Indonesian export potential; Indonesia would have a cost advantage over other possible exporters in supplying ammonia and urea to markets between the east coast of India and the southern half of the People's Republic of China. The Indonesian Government intended to price natural gas from fields too small for liquefied natural gas production but not too small for ammonia, at 50 to 60 U.S. cents per 1,000 cubic feet. There are reportedly a sufficient number of such fields to support any contemplated ammonia production.[23]

Planning continued for the construction in Europe of a 1,650-ton-per-day ammonia plant and a 1,870-ton-per-day urea plant on board two ships, which would then be moored near gasfields off Kalimantan, Borneo.[24] Indonesia's State-owned petrochemical company, P.T. Pupuk Sriwidjaja (PUSRI), also let contracts for the design and construction of a 1,100-ton-per-day ammonia plant and a 1,900-ton-per-day urea plant on the Musi River in Southern Sumatra.[25]

Iran.—A plant to produce 1,320 short tons per day of ammonia was planned as part of the expansion of the Iran Fertilizer Co. at Shiraz. A capacity for 1,650 tons per day of urea and additional facilities for nitric acid and ammonium nitrate were to be included.[26]

Italy.—A new 1,650-ton-per-day ammonia plant, with adjacent urea facilities, will be added to Montedison's complex at Ferrara. Feedstock will be local natural gas, and completion is scheduled for late 1976.[27]

Korea, Republic of.—A $200 to $300 million grassroots fertilizer complex was to be built at Yosu. It will be operated by Namhae Chemical Co. The associated 2,000-short-ton-per-day ammonia plant will be designed by the M. W. Kellogg Co. of Houston Texas, and a urea plant at the site will be designed and constructed by Toyo Engineering of Japan. Startup of the complex is expected in 1977–78.[28]

Mexico.—A 1,000-ton-per-day ammonia plant was brought onstream by Petróleos Mexicanos at Cosoleacaque. Contracts for three additional plants were awarded to the M. W. Kellogg Co.; two of them, also to be located at Cosoleacaque, were of 1,500-ton-per-day capacity, and the third, at Salamanca, was to have a capacity of 1,000 tons per day.[29] The new units were to increase Mexico's ammonia capacity to 6,900 short tons per day by 1977.

Romania.—An ammonia and a urea plant, each with a capacity between 1,000 and 1,500 tons per day, were included in a grassroots fertilizer complex to be erected at Tecuci.[30]

Trinidad and Tobago.—The Prime Minister stated that a 2,000-ton-per-day ammonia plant would be constructed under an arrangement with Amoco; a 1,800-ton urea plant is also to be built in conjunction with the ammonia plant. Also in the consideration stage were proposals for two additional ammonia plants.[31]

United Kingdom.—A decision was reached to construct the Scanitro ammonia plant near Peterhead, Scotland, but the planned size of the plant was reduced to 300,000 to 350,000 tons per year. The project is an equally owned joint venture of Norsk Hydro and Supra UK, a subsidiary of the Swedish firm, Supra AB. The bulk of the output will be exported.[32]

U.S.S.R.—A contract for four ammonia plants, with a capacity of 1,500 short tons each, was awarded by Techmashimport to the French firm Creusot-Loire Entreprises.

Two will probably be near Goglovka in the Ukraine, and the others, at Kemerovo, near Novosibirsk, in Siberia. The plants were originally scheduled to be located at Togliatti, near the plants to be built by Chemical Construction Corp. of the United States under the Occidental Petroleum Corp. barter arrangements, but plants at Togliatti, near Kuibyshev, will be limited to the four by Chemical Construction.[33] The four Creusot-Loire plants will use M. W. Kellogg Co. technology. Two other Kellogg-designed plants, with a capacity of 1,500 tons a day each, went onstream in April and December at Severodovetsk, and Kellogg-designed plants in the U.S.S.R. are now reported to total nine.[34]

TECHNOLOGY

A review of the technical and economic aspects of ammonia production in the light of sharp changes in the availability and price of feedstocks was published.[35] Some 75% to 80% of worldwide ammonia production is obtained via catalytic steam reforming of light hydrocarbons; approximately 60% to 65% of the catalytic steam reforming utilizes natural gas feed. These percentages will more or less be maintained in the near future, but prospects are that over the long range utilization of coal and heavy hydrocarbons will increase substantially. These feedstocks require the noncatalytic partial oxidation process and, especially for coal feedstock, must be based on high ammonia capacity to be competitive; that is, a capacity in the range of 1,000 to 1,500 tons of product per day or even more.

Floating ammonia plants, constructed on vessels to be moored near natural gasfields, are to be tested in a $150 million project (see World Review—Indonesia).

The turndown efficiency of a single-train ammonia plant was discussed; in periods of curtailment of natural gas supplies, turndown or changing temporarily to fuel oil are possible alternatives. Tests showed that process gas consumption remained constant per ton of product, but that efficiency of fuel gas use and overall plant efficiency declined sharply when the plant rate decreased from 90% to 70% capacity. The alternative use of fuel oil to maintain plant output was as efficient as use of natural gas but presented problems of safety and complexity of operation.[36]

A survey of the causes of downtime in ammonia plants was published. Some 27 plants, representing 75% of the large tonnage plants in North America, participated. Major equipment failures were paramount among plants surveyed in 1971–72. Overall reliability of the plants had increased from earlier surveys. Other causes of downtime, such as instrument and electrical failures, were discussed, as well as important reasons for continued increase in reliability.[37]

Peat

By Donald P. Mickelsen [1]

Peat production in the United States increased 15% in 1974, principally because of greater output at several of the larger operations. The number of active operations increased by four, even though two operations were closed due to a lack of environmental permits. Production increased in 18 States; the largest production gains were recorded in Michigan, Illinois, Florida, Indiana, and Minnesota.

Commercial sales of peat in the United States were 14% higher than in 1973. The total value of peat sold, f.o.b. plant, rose 28% to $11.0 million. The average value of all peat sold in 1974 increased $3.40 per ton, principally due to higher fuel, production, and transportation costs.

Imports remained fairly constant in 1974, increasing less than 1%. Imported peat comprised 32% of the peat available for consumption in the United States, a drop of nearly 2% from 1973. Ninety-six percent of the peat imported came from Canada.

World production was estimated at 220.3 million short tons. The U.S.S.R. was the largest producer with an output estimated at 211 million tons, or 96% of the world total.

DOMESTIC PRODUCTION

The 97,000-ton increase in production resulted mainly from a larger output of reed-sedge-type peat. Of the reported production, more than 60% was reed-sedge peat; the remainder was about equally divided between moss peat and humus.

Peat was produced in 23 States in 1974. Michigan remained the largest producer, with about one-third of the Nation's output. Illinois, Florida, Indiana, Pennsylvania, and New Jersey ranked in output in the order named. Together with Michigan, these States accounted for three-fourths of the total production.

Active operations in the United States increased from 98 to 102, and the average output per plant increased 11% to 7,167 short tons. Almost three-fourths of the operations, however, had outputs smaller than the average. Only 32 plants had production in excess of 5,000 tons, and only 5 plants produced more than 25,000 tons.

Production methods in the United States vary with size and conditions of the operation. Virtually all peat was harvested using conventional earthmoving and excavating machinery, or conventional machinery with modifications. Machinery such as power shovels, bulldozers, and front-end loaders was used in drained bogs, while draglines, clamshells and dredges were used in submerged deposits.

Peat deposits, which are generally covered with water, tree trunks, limbs, and other debris, must be properly cleared and drained before harvesting can be started. In most instances, the bog is drained by constructing a series of feeder ditches and collecting canals so that the prevailing water table can be lowered and controlled. Since the surface of the bog is infirm, roads are built on it to provide a firm surface for trucks. Other machinery is equipped with special wide-track treads, enabling it to operate upon the bog surface.

A variety of harvesting methods are

---

[1] Mineral specialist, Division of Coal.

employed at peat operations in the United States. Generally, the peat is harvested by first loosening the top layer of the bog to a depth of approximately one-half inch with a disk, spike, or spring harrow. The loosened peat is then scraped into piles alongside the roads with bulldozers and loaded into trucks with front-end loaders. Other production methods utilize vacuum harvesters, snowblowing machines, draglines, and dredges.

Peat is usually processed for sale by air drying, shredding, and screening, and in a few instances by artificial drying. Processing equipment consists of a variety of screens, shredders, grinders, hammermills, and gas- and oil-fired dryers.

Roughly one-third of the peat was sold as produced with no processing other than air drying. Sixty-eight percent was shredded, and only 1% was subjected to thermal drying.

CONSUMPTION AND USES

Although imports remained at practically the same level, commercial sales increased in 1974 and the amount of peat available for consumption was about 9% greater than in 1973.

Peat was used for a variety of purposes, but 90% of total commercial sales reported by producers were for general soil improvement. Among the principal markets for this peat were nurseries and greenhouses, which used peat as a mulch and a medium for growing plants and shrubs; landscape gardeners and contractors, who used peat for building lawns and golf course greens and for transplanting trees and shrubs; and garden, hardware, and variety stores, which sold peat to homeowners for mulching and improving lawn and garden soils. The remaining peat was sold principally for use in potting soils, for packing flowers and shrubs, and for mushroom beds. Small quantities were also used for earthworm culture, for seed inoculant, and in mixed fertilizers.

Fifty-four percent of the peat sold commercially by producers was packaged and accounted for more than two-thirds of the total value of sales. Package sizes varied greatly, but most producers used 40-pound bags, a change from the 50-pound bags previously used, in order to save on transportation costs. About two-thirds of the packaged peat sold was of the reed-sedge type, one-fifth was humus, and the remainder was moss peat.

States leading in sales of packaged peat were Michigan, Illinois, and Indiana. Together, these States reported 79% of the total sales of packaged peat. Michigan, the largest producer, had 49% of the total sales.

Of the bulk peat, 81% was reported sold for general soil improvement. The remainder of the bulk peat was sold for use in potting soil and for packing flowers and shrubs.

PRICES AND SPECIFICATIONS

Prices of peat at individual operations varied greatly in 1974, with the price depending mainly upon the kind of peat sold, the amount of processing, and whether the peat was sold in bulk or packaged form.

The overall average value per ton, f.o.b. plant, for all peat sold in 1974 was $15.56, up from $12.16 in 1973. The bulk of the increase was attributed to higher average receipts for peat sold by producers in Iowa, New Jersey, Pennsylvania, and Michigan.

The average price of bulk peat increased $1.94 per ton to $10.78. Packaged prices increased an average of $5.12 per ton to $19.69. The average price of bulk peat was influenced mainly by higher overall prices for bulk sales by producers in California, South Carolina, Pennsylvania, and Iowa. The increase in the unit value of packaged peat was attributed to greater receipts for packaged peat sold by Michigan producers.

In a few instances, when producers did not report the value of the peat sold, the sales value was calculated, based upon the average of peat sold within the State.

Imported peat had a total value of $22.6 million. This value was 20% greater than in 1973, partially because there was 3,000 tons more peat imported, but also because the average value per ton increased from $58.00 to $69.16.

Although the average value of imported peat was 4 times that of domestically produced packaged peat, these values are not comparable because of different marketing levels. Also, imported peat has different physical properties than most of the domestic peat, and it is usually sold on a volume basis rather than by weight. Each 100 pounds of a typical air-dryed imported peat will measure approximately 12 bushels, whereas the same weight of a typical domestic peat will measure only 3 or 4 bushels. A few domestic operations produced peat with properties similar to those of the imported kind.

Peat is broadly classified in the United States as moss peat, reed-sedge peat, and humus, varying with the different type of plant materials from which it has been formed and its degree of decomposition. Moss peat is a type that has been formed principally from sphagnum, hypnum, and/or other mosses; reed-sedge peat originated mainly from reeds, sedges, and other swamp plants; and humus peat is too decomposed for identification of its biological origin.

FOREIGN TRADE

The quantity of peat imported into the United States in 1974 totaled 327,000 short tons. This was up 1% from the peat imported in 1973 and was the largest quantity imported in any year to date.

Canada provided the bulk of the peat imports, supplying 96% of the total. Virtually all of the remaining foreign peat was supplied by Europe.

European shipments decreased 17%, principally because of a substantial drop in receipts from West Germany. West Germany supplied 97% of the peat imported from Europe.

Imported peat was classified according to use, either as poultry- and stable-grade peat or as fertilizer-grade peat. Of the total imported, 99% was fertilizer-grade peat. Except for a duty of $0.50 per long ton levied on poultry and stable-grade peat from centrally controlled economy countries, there was no tariff on peat.

Foreign peat entered the United States through 26 customs districts in 1974, but 84% of the total was shipped through the Buffalo and Ogdensburg, N.Y.; Detroit, Mich.; Pembina, N. Dak.; St. Albans, Vt.; and Seattle, Wash., customs districts. The largest quantity 90,000 tons, was shipped through the Ogdensburg district.

WORLD REVIEW

World production of peat in 1974 was estimated at 220 million short tons, remaining at practically the same level as the revised output reported for 1973.

The U.S.S.R. was by far the largest peat producer, with an estimated 96% of the world production. According to published U.S.S.R. figures, 145 million tons of peat was produced by state enterprises for agricultural use, and an estimated 66 million tons was used for fuel. Agricultural peat was used for general soil improvement and the manufacture of fertilizers, and fuel peat was used for generating electric power and for domestic and industrial heating.

Ireland ranked second in peat production, with an estimated output of 4 million short tons. Virtually all of Ireland's production was fuel peat that was used for generating electric power and for heating households. A small amount of agricultural peat was produced, principally for export.

West Germany, the third-ranking peat producer with 2.3 million tons, provided about 2% of the world output. Most of the West German production was agricultural peat, with only 10% consumed as a fuel.

Other producers, ranking in output in the order named, were the United States, Finland, the Netherlands, and Canada. The combined output of these countries was, however, only 1% of the world total. Although the United States was fourth in world production, its output was less than one-half percent of the world total.

[1] In addition to the countries listed, Austria, Canada, Iceland, and Italy produce a negligible quantity of fuel peat. No data are available for East Germany, a major producer.

TECHNOLOGY

Results of research conducted by the State of Minnesota at Wilderness Valley Farms and at the Virginia sewage treatment plant, together with technical advice from Dr. Rouse Farnham of the University of Minnesota, led to the construction of peat-over-sand sewage treatment filters at four U.S. Forest Service campgrounds in Minnesota. These sewage treatment facilities have been in operation since January 1973, and have been constantly monitored under Environmental Protection Agency (EPA) requirements. Results show that the filters meet all EPA guidelines, removing 99.8% of the phosphates and nitrogen and eliminating almost 100% of the Biochemical Oxygen Demand and coliform bacteria. The peat-over-sand filters are inexpensive and effective and are capable of handling the sewage produced from a community of up to 3,500 people.[2]

The Minnesota Gas Co. has proposed to convert peat into synthetic natural gas (SNG), following preliminary studies and research conducted by the Institute of Gas Technology on peat gasification. Gas can be produced from the incomplete combustion of peat in the presence of hot air and steam. The resulting gases are cleansed of ash and tar by means of scrubbers, and pure ammonia and hydrogen sulfate are produced as byproducts. The remaining gases undergo a shift conversion, producing an intermediate calorific gas which is upgraded by a methanation process to SNG.

The Minnesota Gas Co. has applied for a 25-year lease from the Minnesota Department of Natural Resources on 200,000 acres of State-owned peat bogs, averaging about 7½ feet in thickness.

Further research needs to be conducted to determine the economic feasibility of producing SNG from peat. If the process is proved to be commercially feasible, a demonstration plant is planned with a capacity of up to 80 million cubic feet per day (MMCFD).

---

[2] Department of Iron Range Resources and Rehabilitation, State of Minnesota. Biennial Report 1972–1974. P. 15.

A full-scale peat gasification plant would produce an estimated 250 MMCFD, equal to an annual output of approximately one quarter of the natural gas consumed in the State in 1974. An operation of this size would have an estimated 20-year supply of peat available from the requested lease, if the plant was operated on a continuous basis.[3]

In experimental research conducted at British Columbia Research, Vancouver, Canada, Canadian sphagnum peat moss was tested for its adsorption capacity of odorous gases. In these studies, 20-mesh sphagnum peat was first degassed by heating to 103° C for 6 hours, after which its capacity was compared with that of Dargo G-60, an adsorption type of 20 to 40 mesh activated charcoal.

Three gases–dimethylamine, ammonia, and hydrogen sulfide—were chosen as test materials because of their odor and extensive use in many industrial operations. These gases, using helium as a carrier, were passed through adsorption columns filled with equal volumes of peat or activated charcoal. The experiments were monitored by a thermal conductivity detector, and results indicated that peat had 30% to 38% the adsorption capacity of activated charcoal on a volume basis. On a weight basis, however, peat had 80% to 97% the adsorption capacity of activated charcoal.

According to British Columbia Research, the capacity of peat as an adsorbent of odorous gases has several disadvantages when compared with the capacity of activated charcoal. Because peat is only 2.6 times as dense as activated charcoal by weight, a peat filter would have to be almost 3 times bulkier than one of activated charcoal to achieve the same effectiveness. Also, the effective life of peat filters were found to be only 14% to 23% as long as the life of activated charcoal filters. This means that peat filters would have to be replaced 4 to 7 times more often than those of activated charcoal. British Columbia Research concluded from the studies that sphagnum peat was not a feasible substitute for activated charcoal for adsorbing odorous gases.[4]

Perlite

By Arthur C. Meisinger [1]

A record quantity (555,000 tons) and value ($7.0 million) for crude perlite sold and used were set in 1974 by the domestic industry. The previous record year was 1972. Deposits in New Mexico supplied 88% of the total crude perlite ore mined (676,000 tons) in 1974.

The value of expanded perlite sold or used at 76 plants in 30 States was a record $30.7 million, compared with $28.0 million in 1973 and the previous record of $28.4 million in 1972. Illinois continued to be the leading State in the production of expanded perlite.

Grefco, Inc., announced plans to reopen its Socorro, N. Mex., perlite operation, which is expected to be on-stream by late 1975.

Table 1.—Crude and expanded perlite produced and sold or used by producers in the United States

(Thousand short tons and thousand dollars)

Year	Crude perlite						Expanded perlite		
	Quantity mined	Sold		Used at own plant to make expanded material		Total quantity sold or used	Quantity produced	Sold or used	
		Quantity	Value	Quantity	Value			Quantity	Value
1970 ----	607	176	2,056	280	2,848	456	420	416	24,972
1971 ----	495	175	2,062	257	2,879	432	389	385	23,156
1972 ----	649	224	2,540	321	3,691	545	427	421	28,397
1973 ----	759	238	2,771	306	2,819	544	424	418	28,005
1974 ----	676	275	3,544	280	3,480	555	423	419	30,747

DOMESTIC PRODUCTION

Production of crude perlite in 1974 was reported by 11 companies in 6 States, 1 less than in 1973. Twelve mines were in operation—the same as in 1973. The quantity of crude ore mined in 1974 was 676,000 tons, or 12% below the record quantity of 759,000 tons in 1973. New Mexico, with 88% of the U.S. crude perlite mined, continued to be the principal producing State, followed by Arizona, California, Nevada, Colorado, and Idaho in descending order.

A record quantity of 555,000 tons of crude perlite was sold and used in 1974. The previous record quantity was 545,000 tons in 1972. Value of crude perlite sold and used was also a record figure of $7.0 million, and exceeded by $793,000 the previous high value of $6.2 million in 1972.

As in 1973, perlite was expanded at 76 plants in 30 States. The quantity produced was 1,000 tons less than the 424,000 tons produced in 1973, and the quantity sold or used (419,000 tons) was 1,000 tons more than that of 1973. The value of expanded perlite sold or used reached a record $30.7 million.

The leading States in descending order of expanded perlite production in 1974 were Illinois, Mississippi, Kentucky, Pennsylvania, Colorado, Florida, New Jersey, Texas, California, and Indiana.

---

[1] Industry economist, Division of Nonmetallic Minerals.

Grefco, Inc., Los Angeles, Calif., announced plans to reopen its Socorro perlite deposit and processing plant. Mining was begun at Socorro in 1947, and was discontinued in 1961 when operations were consolidated at No Agua, N. Mex., and Antonito, Colo. The Socorro facilities are expected to be operational in late 1975.

[1] Includes Colorado, Georgia, Idaho, Illinois, Iowa, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Nebraska, Nevada, New Hampshire, New Jersey, Oregon, Tennessee, Utah, and Wisconsin.

CONSUMPTION AND USES

Consumption of expanded perlite in 1974 was 419,500 tons, or 1,645 tons more than in 1973. The percent disposition by end use is shown in table 3. Filter aids was again the principal use for expanded perlite, although showing a decline of 2% from 1973 consumption. Plaster and concrete aggregates, combined, at 17% were unchanged. Other primary end uses for expanded perlite showed gains in 1974, with the exception of fillers (1% decline) and formed products (no change). Other uses totaled 42% compared with 46% in 1973, and included primarily insulation board and such uses as paint textures, foundry castables and bonding agents, polishing compounds, and fines for various industrial applications.

Table 3.—End use of expanded perlite

(Percent)

Use	1973	1974
Filter aid	19	17
Plaster aggregate	10	9
Concrete aggregate	7	8
Horticultural aggregate	5	6
Low-temperature insulation	2	5
Masonry and cavity fill insulation	1	4
Fillers	2	1
Formed products	8	8
Other [1]	46	42

[1] Includes insulation board.

PRICES

Producers sold crushed, cleaned, and sized crude perlite at expanding plants at an average price of $12.89 per ton in 1974, and that portion used by producers in their own expanding plants was valued at an average of $12.43 per ton. The weighted average price of both categories was $12.66 per ton—an increase of $2.38 over that of 1973.

Expanded perlite sold or used, according to expanders, increased in average value by 9.5% in 1974, compared with the 1973 average value of $67.02 per ton. Average values by States in 1974 ranged from $28 to $174 per ton, compared with the 1973 range of $34 to $151 per ton.

WORLD REVIEW

Greece.—Although data on perlite production were not available for 1974, a substantial increase in the production of both crude and screened perlite was achieved in 1973, compared with that of 1972. Crude perlite production in 1973 was 273,300 tons, or 136,800 tons more than in 1972. Processed (screened and sized for export) perlite production was 138,600 tons in 1973, compared with 120,300 tons in 1972.

Hungary.—Production of crude perlite was 105,500 tons in 1973, compared with the last reported production of 67,100 tons in 1971. Data on perlite production in 1974 were not available.

Mexico.—The country produced approximately 14,900 tons of crude perlite in 1973, compared with 14,200 tons in 1972. Production data for 1974 were not available, but were expected to be above the 1973 figure.

Taiwan.—A perlite-expanding plant was reported to be in operation in Taipei. The plant is owned by Kei Hsing Chemical Industries, Ltd., Taiwan.[2]

The energy supply situation in general and the petroleum-supply situation in particular became major concerns of the public soon after the Arab oil embargo began in 1973. That concern carried over into 1974. Although the embargo was lifted in March, the experience with long lines of cars at service stations had an impact on the consumer that did not moderate until mid-1974. With conservation a prime consideration, mild winter weather, and rising prices, domestic demand for petroleum products averaged 16.6 million barrels per day (bpd), nearly 4% less than the 17.3 million bpd of 1973 (each barrel contains 42 gallons).

Volumewise, most of the decline in demand was in residual fuel, distillate fuel, and motor gasoline. Refinery runs declined, but with demand down and imports at high levels, yearend stocks of most major products were substantially higher than those of 1973.[4]

Crude oil production in 1974, including lease condensate, declined to 8.8 million bpd, nearly 5% below the 1973 production of 9.2 million bpd. The reduction can be attributed at least in part to the gradual depletion of older fields, coupled with an inability to discover any major new fields.

[4] Certain terms as used in this chapter are more or less unique to the petroleum industry. Principal terms and their meanings are—

Total demand.—A derived figure representing total new supply plus decreases or minus increases in reported stocks. Because there are substantial consumers' stocks that are not reported to the Bureau of Mines, this figure varies considerably from consumption as reported by the Federal Highway Administration of the Department of Transportation.

Domestic demand.—Total demand less exports.

New supply of all oils.—The sum of crude oil production, plus production of natural gas liquids, plus benzol (coke-oven) used for motor fuel, hydrogen, and other hydrocarbons, plus imports of crude oil and other petroleum products.

Transfers.—Crude oil conveyed to fuel-oil stocks without processing, or reclassification of products from one product category to another.

All oils.—Crude petroleum, natural gas liquids, and their derivatives.

Exports.—Includes shipments to the United States territories, possessions, and free trade zones.

Imports.—Includes receipts from the United States territories, possessions and free trade zones.

The decline in production made it necessary to increase imports in order to meet demand requirements. Imports of crude oil continued to rise. In 1974, crude oil imports averaged 3,477,137 bpd, which was 7% above 1973 imports and 56% higher than in 1972, when there was no embargo. Four lease sales were conducted in 1974 by the Bureau of Land Management of the U.S. Department of the Interior. These sales, held in March, May, July, and October, involved 1,762,158 acres, and the bonuses aggregated about $5 billion.

Drilling activity accelerated in 1974. The weekly activity of 1,474 rotary rigs was the highest in 10 years, according to the Hughes Tool Co. The American Petroleum Institute (API) reported there were 12,784 oil wells completed in 1974, an increase of 29%. The 7,240 gas wells drilled in 1974 was 13% higher than in 1973. It should be noted that a very large part of this rig activity related to infill development drilling; that is, drilling in known fields. Much of this activity was attributable to the "two-tier" pricing of crude oil. On one tier is "old" oil at $5.25 per barrel; on the other tier is "uncontrolled oil, classified as "new," "released," or "stripper," priced in December 1975 at $12.95 per barrel. Much of this development-well drilling involves production of new oil.

According to API estimates, reserves of crude oil declined for the fourth consecutive year as production withdrawals continued to outstrip additions to reserves. Reserves of 34.2 billion barrels at yearend 1974 represented a reserves-to-production ratio for crude oil of 11:1 (based on 1974 production). The largest single addition to reserves occurred in 1970 when the Alaska North Slope discoveries were included for the first time. Since World War II, reserves-to-production ratios have trended downward from a high of 13.6:1 in 1949 to a low of 9.2:1 in 1969.

Refinery throughout capacity at yearend 1974 amounted to 14.9 million bpd, up 4.9% from yearend 1973. Following the discontinuance of import quotas on crude oil and petroleum products in early 1973, many refiners announced expansion plans that could increase throughput capacity by nearly 1.2 million bpd by the end of 1976. Most of the proposed new capacity is scheduled to use imported crude oil.

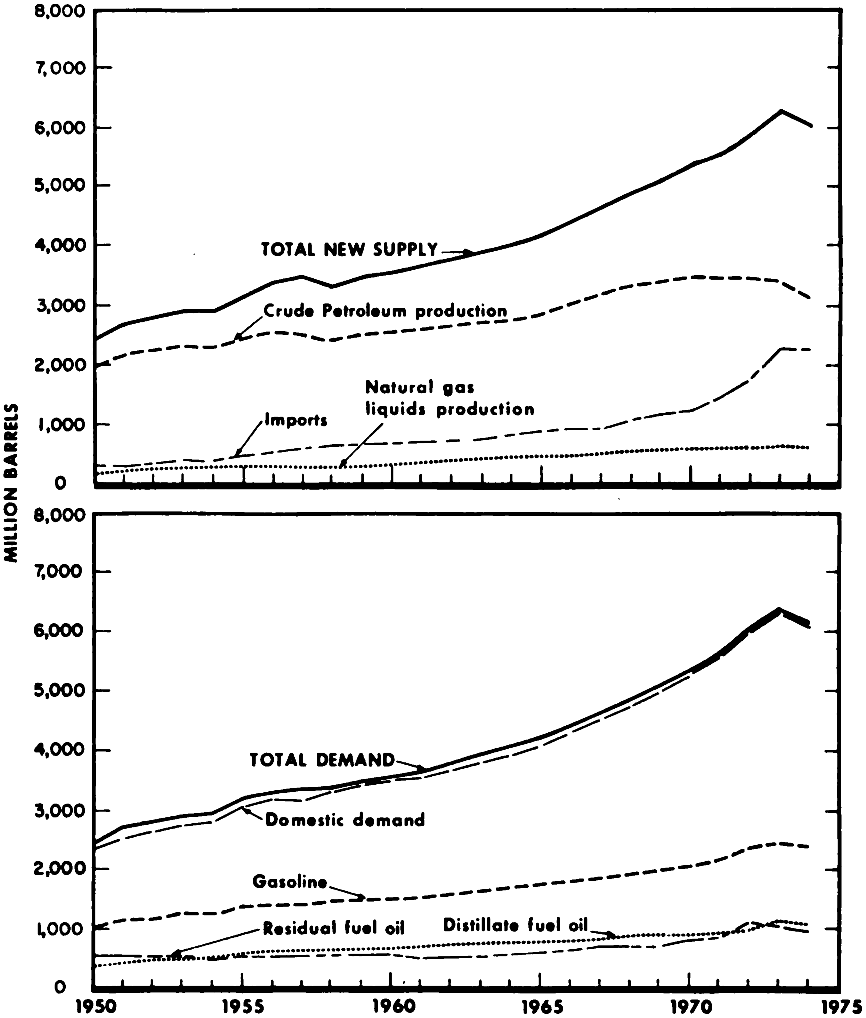

Figure 1.—Supply and demand of all oils in the United States.

CRUDE PETROLEUM

PRODUCTION

Production of crude oil (including lease condensate) in 1974 continued the downtrend that began after 1970. Total production in 1974 was about 3.2 billion barrels, nearly 5% below that of 1973. There were declines in 18 of the 31 oil-producing States. The sharpest decline occurred in the gulf coast region of Louisiana, which had a drop of 93 million barrels, or nearly 12%. In Texas, gains in Texas Railroad Commission district 06 (excluding East Texas) and district 08A (West Texas) failed to offset declines in other districts, so there was a net decline in 1974 of 32.5 million barrels.

The decline continued in 1975. On the plus side production rose 6.7 million barrels, or nearly 21% in Utah, and production in Florida continued to increase (11%) to 36.4 million barrels in 1974. Other comparisons are shown in table 5. In early 1975, production in Michigan was substantially above 1974 levels; likewise, Florida continued to make gains over the 1974 production levels.

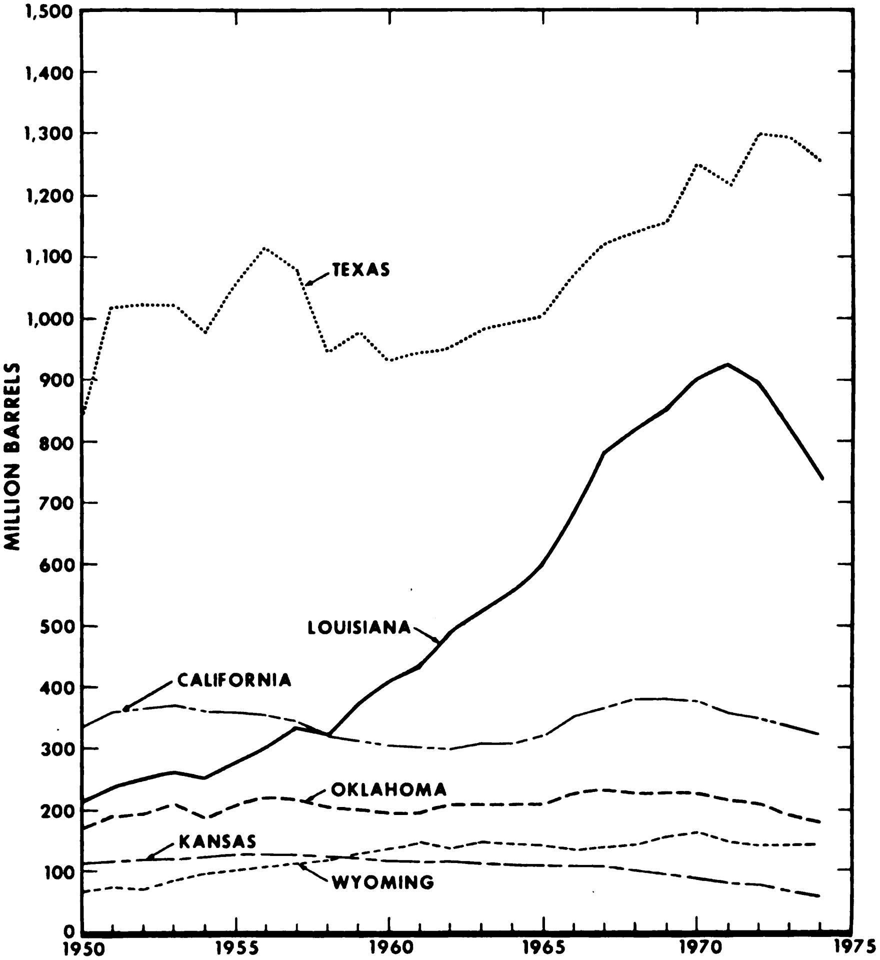

Figure 2.—Production of crude petroleum in the United States, by principal producing States.

CONSUMPTION

Crude oil refineries processed 4.4 billion barrels (12.1 million bpd) of crude oil, of which 71.5% was domestic crude and lease condensate and 28.5% originated in foreign countries (table 16). Based on operable refinery capacity as of January 1, 1974, of 14.4 million bpd, refineries in the United States operated at 85.3% of capacity during 1974.

PRODUCTIVE CAPACITY

According to API, the maximum crude oil output that could be attained in the United States as of December 31, 1974 was about 8.9 million bpd. This was the lowest since 1960 and 8.7% less than that on December 31, 1973. Texas and Louisiana suffered a combined loss of 771,000 bpd. Florida, Michigan, Utah, and Ohio increased productive capacity by a total of 45,000 bpd. These estimates were based on the assumption that such production could be achieved in 90 days with existing wells, well equipment, and present surface facilities, plus work changes that could be accomplished within that time. No productive capacity was credited to the North Slope of Alaska since there is no way to market the oil until the trans-Alaska Pipeline is operational.

For many years, the United States had a surplus productive capacity that could be called on to meet emergency needs, but with production declining and demand rising, there is little likelihood of a return to excess production capacity within the foreseeable future.

DRILLING ACTIVITY

Drilling activity revived markedly in 1974 and successful oil and gas completions totaled 20,024 wells, a 23% increase. Most of these gains occurred in oil well completions; this was the first time in 10 years that the yearend total was higher than at the end of the previous year. There were 12,784 oil wells completed in 1974, a 29% increase of nearly 2,900 wells. Gas well completions were up 855, 13% above the 1973 results.

Development well completions increased 29% above 1973 levels and accounted for 11,970 wells, or nearly 94% of total oil well completions in 1974. More than 4,100 (34%) of the total successful oil wells were completed in Texas. More than 1,600 of the Texas total were located in Texas Railroad Commission districts 08 and 08A in West Texas. California was second in importance with 1,539 oil well completions, a 78% increase over 1973 levels. East-central California accounted for about 1,200 of the completions in that State. In Oklahoma, development-well drilling revived; there were nearly 1,100 completions compared with 860 in 1973.

Development oil well completions for 1970–75 are shown in the following tabulation, by quarter:

Year	Jan.–Mar.	Apr.–June	July–Sept.	Oct.–Dec.	Total[1]
1970	3,088	2,948	3,115	3,125	12,230
1971	2,804	2,679	2,617	3,089	11,207
1972	2,789	2,726	2,664	2,452	10,622
1973	2,310	2,093	2,333	2,542	9,283
1974	2,417	2,949	3,196	3,396	11,970
1975	3,515	3,270	3,755	4,868	15,436

[1] Quarterly reports, as published do not add to totals shown because of subsequent revisions.

Source: Quarterly Review of Drilling Statistics for the United States. American Petroleum Institute, Washington, D.C.

The uptrend in oil well drilling continued in 1975 and there were 15,436 development wells, a 29% increase over 1974.

There were about 497,631 oil wells producing at the end of 1974 compared with 497,378 at yearend 1973. This is the first time in nearly a decade that an increase occurred in the number of oil wells producing. From 589,203 wells in 1965, the number eroded to the low in 1973.

Stripper wells, which are wells producing 10 bpd or less of oil, accounted for about 355,000, or 70%, of all oil wells. Production of all producing oil wells averaged 17.6 bpd in 1974.

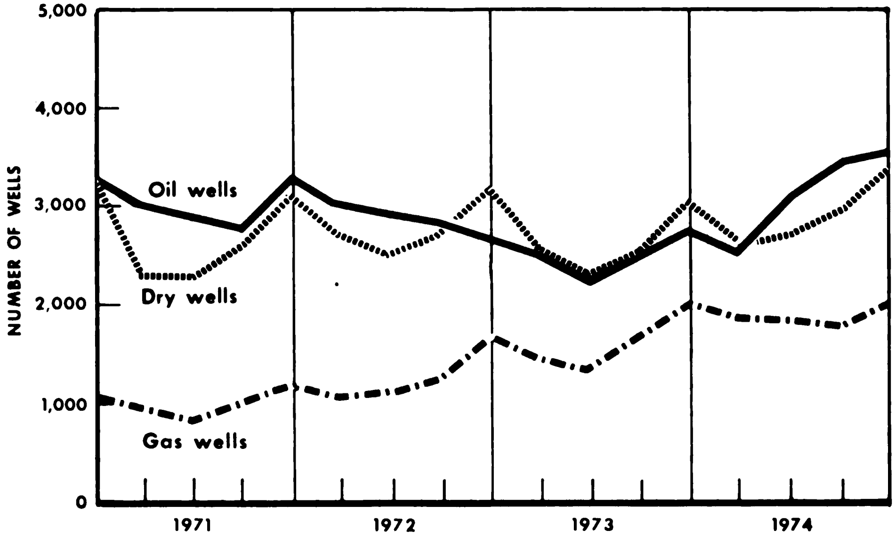

Figure 3.—Wells drilled for oil and gas in the United States, by quarter.

RESERVES

The API Committee on Petroleum Reserves and Productive Capacity estimated proved recoverable reserves of crude oil as of December 31, 1974, to be 34,250 million barrels, a decline of 1,050 million barrels for the year.

Gains in proved reserves occurred in seven States, led by Florida, which added 119 million barrels. Losses in proved reserves occurred in 16 States. In those States having significant reserves, the largest losses occurred in Texas (755 million barrels), Louisiana (350 million barrels), Oklahoma (39 million barrels), and Mississippi (nearly 30 million barrels).

According to API, indicated additional reserves from known reservoirs amounted to 4,636 million barrels. These are potentially available crude oil reserves in known reservoirs in excess of the proved reserves. Engineering knowledge and judgment indicate that these additional reserves will be economically available by application of fluid injection and other improved recovery techniques. Most of the indicated additional reserves were in Texas (2,032.6 million barrels), California (1,348.6 million barrels), New Mexico (311.5 million barrels), Louisiana 224.5 million barrels), and Oklahoma (205 million barrels).

In addition to proved reserves and indicated reserves, there are "inferred" reserves and estimates of undiscovered recoverable resources. The U.S. Geological Survey estimated inferred reserves at 23.1 billion barrels as of December 31, 1974. These reserves are estimated to be recoverable in the future as a result of extensions and revisions of estimates and new pays in known fields beyond those shown in indicated reserves shown in table 12. The category of undiscovered recoverable resources includes deposits that are yet to be discovered but are assumed to be economically producible. These resources also include deposits that are already identified but cannot be extracted now because of economic or technological factors. It should be noted that the estimates shown in table 13 are based on price-cost relationships and technological trends prevailing in the recent years prior to 1974.

Crude Supply.—Total receipts of crude oil at refineries in 1974 were 4,436.3 million barrels, or 12.2 million bpd, a decrease of 109.5 million barrels, or 300,000 bpd, for the year. Refinery runs to stills decreased 108.5 million barrels, or 297,000 bpd, in 1974 as shown in table 18. Overland receipts of foreign crude oil (from Canada) were 76.6 million barrels lower in 1974; foreign receipts from overseas sources increased 161.8 million barrels, or 443,200 bpd.

More foreign overseas crude oil entered refineries in all PAD districts in 1974 because domestic crude oil was in short supply. Refineries processed 4,428.7 million barrels of crude oil in 1974, reported a net of 1.3 million barrels used for refinery fuel and as losses, and added 6.3 million barrels to stocks (table 18).

REFINED PRODUCTS

The Arab oil embargo was in full effect during the first 3 months of 1974, significantly reducing imports of crude oil and refined products below normal levels and causing some shortages. Although imports resumed after March, gasoline demand revived slowly. The recession also caused demand to taper off. As a result, overall domestic demand for petroleum products in 1974 dropped 3.9% to 16.6 million bpd, from the 17.3 million bpd in 1973.

MOTOR GASOLINE

Restrictions on availability of motor gasoline in the first quarter of 1974 had a traumatic effect on gasoline buyers through June 1974. As a result, gasoline demand did not revive until July. Hence, in 1974, gasoline demand declined to 6.5 million bpd, or 137,000 bpd below that of 1973, but still above 1972 levels. During this period, Federal Energy Administration (FEA) gasoline supply and use restrictions were in effect. Under the Emergency Petroleum Allocation Act of 1973 (P.L. 93-159), FEA set up allocation levels for fuels (including gasoline). The allocation level for each wholesale purchaser was 100% of current requirements for certain priority uses, such as energy production, emergency uses, agriculture, and transportation. Other businesses, such as industrial, commercial, governmental, and social-agency users, were to receive 100% of 1972 consumption. There was also a 3% State set-aside to provide a reserve for emergency needs; it was to be administered by the States. Still other factors contributing to soft demand have been rising gasoline prices and the impact of the recession on the use of passenger cars, trucks, and buses.

Motor fuel consumption in the United States during 1974, as estimated by the Federal Highway Administration, averaged 7.2 million bpd. This differs from the Bureau of Mines estimate of 6.5 million bpd because the Bureau data did not include changes in secondary stocks. Gasoline users, after waiting in long lines at gasoline service stations during late 1973 and early 1974, adopted a new policy of operating cars with full or nearly full gasoline tanks. The allocation however, of gasoline by priority was unnecessary in 1974 because supplies increased. When demand failed to offset production, refiners cutback on gasoline production.

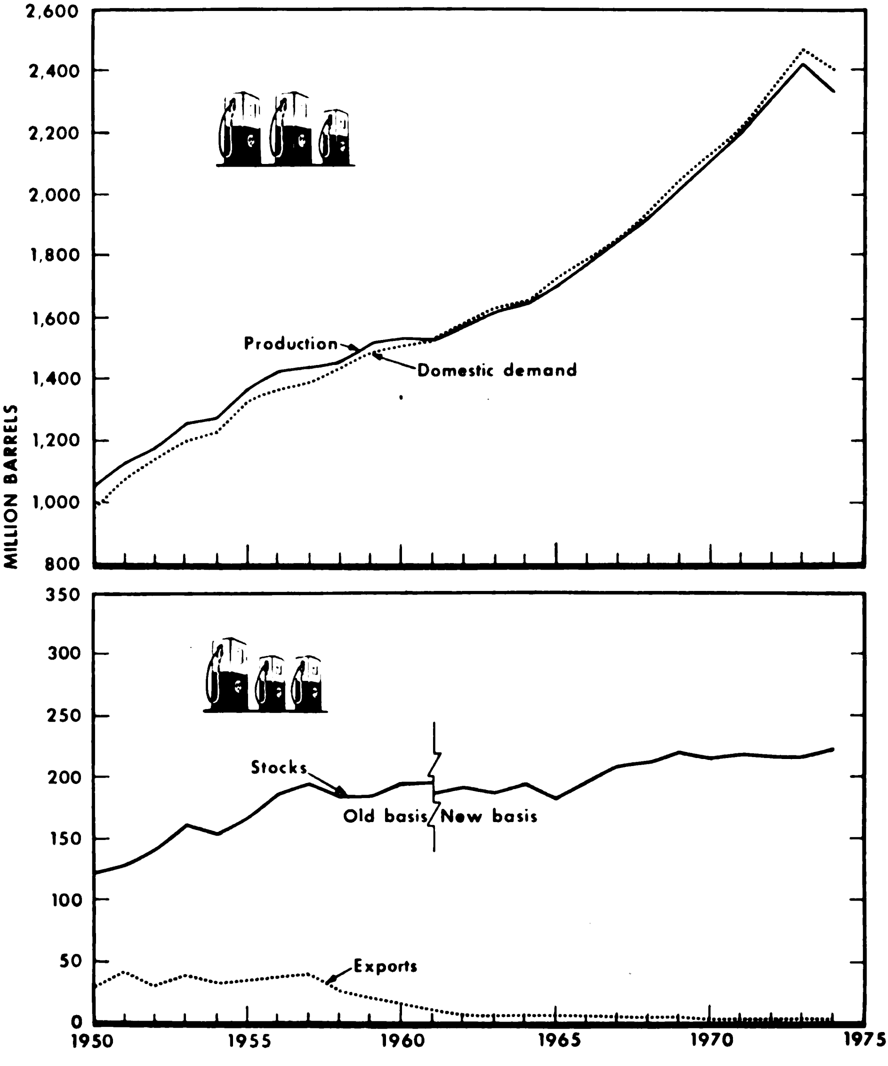

Figure 4.—Production, domestic demand, stocks, and exports of gasoline in the United States.

AVIATION FUELS

Aviation Gasoline.—The downtrend in demand, which dates back nearly a decade, appears to have leveled off. With the transition from piston to jet and propeller-jet engines, demand shrank 63% from 120,000 bpd in 1965 to 44,000 bpd in 1974. Over this period, airline use of aviation gasoline declined from 33,000 to 4,200 bpd; military use declined from 60,000 to 13,700 bpd. Military use accounted for 53% of demand in 1965 and about 31% in 1974 as shown in table 27.

Commercial Jet Fuel.—By far, the greatest use of kerosine is in commercial kerosine-type jet fuel. This product is a kerosine with restrictions on the content of aromatics and naphthas as stipulated in ASTM-D1655 specifications. The product has a very low freezing point and includes military JP-5 jet fuel.

The drastic cuts in commercial airline flights resulting from the Arab oil embargo had a severe impact on use of commercial jet fuel. Shipments of this fuel dropped nearly 8% from 753,000 to 694,000 bpd in 1974 as evidenced in table 28.

About 26,000 bpd of naphtha-type jet fuel was used commercially, primarily by the airlines. Naphtha-type jet fuel is in the heavy-naphtha boiling range, with an average gravity of 52.8° API and 10% to 90% distillation at 210° F to 420° F, and conforms to ASTM–D1655 and military specifications MIL–F–5624 and MIL–T–56246. It includes military jet fuel, JP–4. Military use of jet fuel in 1974 averaged 234,000 bpd, slightly less than the 235,700 bpd of 1973. However, shipments of naphtha-type jet fuel were nearly 8 million barrels higher in 1974 than in 1973. In addition, the military imported another 8 million barrels into PAD districts I and V.

The allocation program, administered by FEA, was changed as more supplies became available. The most recent change occurred in July 1974. Under the revision, applicable to aviation fuels, 100% of requirements were allotted to the Department of Defense. Agricultural production flying, emergency aviation service, safety and energy missions, energy production flying, telecommunications flying, and aircraft manufacture were allotted 100% of current requirements as reduced by an allocation fraction. All other categories since July 1974 received 100% of base-period use, as reduced by an allocation fraction.

Peaking Unit Use.—In addition to the conventional uses of kerosine-type jet fuel, the use of jet engines as gas turbines to generate electric power is expanding, but use of jet fuel is decreasing. For example, about 4.3 million kilowatts of capacity in gas turbine plants was either in the planning stage or under construction in 1974. Another 1.5 million kilowatts was scheduled for 1975. Conversely, nearly 5.2 million barrels of kerosine-type jet fuel was used by electric utility companies in 1974, 6.3 million barrels in 1973, and 8.8 million barrels in 1972. Data for previous years are not available. Virtually all of the kerosine-type jet fuel was used in peaking units of electric utilities. Although gas turbine capacity of peaking units has expanded, the sharp increase in prices is inducing the utilities to use Nos. 2 and 4 distillates and cutback on use of commercial kerosine-type jet fuel.

LIQUEFIED GASES, ETHANE, AND ETHYLENE

Liquefied gases are derived from two sources; those produced at refineries are called liquefied refinery gases to distinguish them from liquefied petroleum gases obtained by processing natural gas. The liquefied petroleum gases (LPG) are all paraffins (propane, butane, and isobutane). The liquefied refinery gases (LRG) also contain paraffins, but may also contain unsaturated hydrocarbons; that is, the olefins (propylene, butylene, ethylene, etc.). The paraffins may be used as fuel (including as a blend with motor gasoline) or as feedstock at petrochemical plants. The olefins are used primarily as petrochemical feedstocks.

Demand for ethane (including ethylene) increased 4.3% in 1974. Use of ethane as petrochemical feedstock increased demand from 327,200 bpd in 1973 to 341,300 bpd in 1974.

Domestic demand for LPG and LRG in 1974, excluding that blended into other products at refineries or terminals, was 1,063.7 million bpd compared with 1,121.4 million bpd in 1973. Propane accounted for 78% of liquefied gas demand in 1974.

Major natural gas consumers (industrial firms, electric powerplants, and natural gas utilities), fearing a shortage of natural gas, sought propane as a substitute or standby fuel and were active propane purchasers. This represented a significant demand for propane and some diversion of propane from established markets.

A mandatory propane allocation program was effected on October 3, 1973. This program has been successful in terms of supply. Propane was available during the heating season because of the combined effects of allocation, high prices, mild winter weather, and the economic recession. Furthermore, stocks of propane, totaled 64.7 million barrels at yearend, which was 8% over those of 1973. In 1975, however, production of propane and other natural gas liquids was affected by the decline in natural gas production.[5]

---

[5] Data are available for 1975 in the following Bureau of Mines, Mineral Industry Surveys: Natural Gas, Monthly; Natural Gas Liquids, Monthly; Petroleum Statement, Monthly.

KEROSINE

A mild winter coupled with changeovers to other types of heating contributed to the 18.5% drop in demand to 176,300 bpd. In 1974, refiners cutback on production 62,400 bpd, or 29% less than the 1973 level of about 280,000 bpd. The same allocation regulations applicable to distillate fuel oil applied to kerosine.

The primary use for kerosine (including range oil) is space heating. Although space heating accounted for 78% of the domestic demand for kerosine, that demand has been in a downtrend for many years. However, this trend may be arrested or begin to flatten out if present users decide not to convert to the more convenient forms of energy such as LPG and electric power because of sharp increases in the prices of LPG and electricity.

DISTILLATE FUEL OIL

When produced in conventional distillation procedures, distillate has a boiling range from 10% at 300° F to 90% at 675° F. Included are Nos. 1 and 2 heating oils and diesel fuels. No. 4 fuel oil, which is a blend of distillate fuel oil and residual fuel oil, is used extensively in industrial plants because it does not require preheating.

Demand for distillate declined 5% to 2.9 million bpd in 1974. Most of this decline reflected reduced use of distillate for heating as shown in table 32, because of a mild 1973–74 winter. Some of the decline resulted from a lower demand for diesel fuel for on-highway use. Most uses of distillate were lower in 1974 except for sales to electric utility companies.[6] Most of this increase resulted from restrictions on the use of high-sulfur-content fuels such as coal and residual fuel oil. Utilities are also using sizable quantities of distillates in their gas-turbine and internal-combustion generating engines as shown in table 32.

Although stock levels, in terms of days' demand, were at low levels in March and April, inventories during the remainder of the year were at or above normal levels, as shown in table 33.

Allocation of distillate by FEA as amended July 1974 established the following priorities:

(1) Agricultural production, nonhousekeeping uses by the Department of Defense, and space-heating requirements of medical and nursing buildings for all purposes were allotted 100% of requirements.

(2) Emergency services, energy production, manufacture of ethical drugs and related research, sanitation services, telecommunications services, passenger transportation services, cargo, freight, and mail handling, aviation ground support vehicles and equipment, nonmilitary marine shipping, industrial uses except space heating, petrochemical-feedstock use, and space-heating requirements were allotted 100% of current requirements reduced by an allocation fraction.

(3) An amount of 100% of base-period use as reduced by an allocation fraction was allotted for synthetic natural gas (SNG) plant-feedstock use, electric utilities, and all other nonspace-heating uses.

RESIDUAL FUEL OIL

Residual fuel oil demand in 1974 declined 198,000 bpd, 7% below 1973 demand. Heating, which accounted for 17% of residual fuel oil demand, declined 68,000 bpd, or 12%, below 1973 levels; there was a 7% decrease of 95,000 bpd in electric utility use. Utilities accounted for nearly 50% of residual fuel oil sales in 1974. Some of this decline reflected a mild winter, but the economic recession was also a factor.

Domestic refinery production of residual fuel oil totaled 1.1 million bpd, a 10% increase over that of 1973 as shown in table 34. Residual oil with a sulfur content of less than 0.5% accounted for 267,592 bpd, or 25%, of production. Imports of residual oil were more than 100 million barrels, or 280,000 bpd less than in 1973. Residual fuel oil with less than 0.5% sulfur made up nearly 37% of residual fuel imports. Caribbean refiners supplied 435,000 bpd, or 80%, of low-sulfur residual fuel.

Stocks were at adequate levels. At the end of 1974, they were equivalent to a 20-day supply based on April 1975 demand, and equivalent to a 30-day supply compared with 21 days in April 1974.

Residual fuel oil allocations were similar in most instances to those previously outlined for distillate fuel oil. However, there were exceptions, such as the allocation level specified each month by FEA for utility use. In specifying allocation levels for each utility, FEA may include, but is not limited to, considerations such as the following: (1) Each utility shall absorb an equal percentage of the cutback in electricity generation; and (2) electric generating plants now burning residual fuel oil have been identified by FEA for conversion to coal.[7]

OTHER PRODUCTS

Petrochemical Feedstocks.—In 1974, petroleum refineries produced nearly 134.8 million barrels of petrochemical feedstocks. Domestic demand approximated 132.5 million barrels, slightly more than in 1973. Naphtha–400° constituted nearly 47% of demand in 1974, as indicated in table 35.

Still Gas.—Still gas is a mixture of extremely low-temperature-boiling hydrocarbons produced during the distillation of crude oil and may be used as refinery fuel and/or as a petrochemical feedstock. During 1974, refineries used 175,724,000 barrels of still gas as fuel, a nominal decrease from the 176,758,000 barrels consumed in 1973.[8] Consumption of still gas as a petrochemical feedstock increased 15.6% to 14,375,000 barrels from 12,428,000 barrels in 1973 and the uptrend continued in 1975.

Special Naphthas.—Special naphthas are used primarily as paint thinners, cleaning agents, and solvents. In 1974, as shown in table 36 domestic demand was 31,976,000 barrels, a shade below the 32,230,000 barrels in 1973 and the decline became even more pronounced in 1975.

Lubricants.—Domestic demand for lubricants declined about 4% to about 56.7 million barrels as shown in table 37 in 1974; so did total demand, as exports dropped to 11,936,000 barrels, 6% below shipments abroad in 1973. Lubricating oils accounted for nearly 98% of lubricant exports; greases accounted for the remainder. Part of the decline in demand reflected the decline in industrial activity. Industrial uses for lubricating oils and greases were slightly above the volumes for automotive and aviation use.

Waxes.—Demand for waxes slackened in 1974 to 6,801,000 bpd a decline of 2.8% from the 6,941,000 bpd of 1973, as indicated in table 38. The economic recession and the decline in business is reflected in weak wax demand. Paper converting accounts for 50% of wax end use.

Petroleum Coke.—Petroleum coke is reported by the Bureau of Mines as catalyst coke and marketable coke. Catalyst coke is a noncommercial coke; it cannot be recovered and marketed because it forms on the catalyst during the catalytic cracking of charging stock in the cracking unit of a refinery. This carbon is burned off the catalyst in the regenerator section of a cracking unit, and the coke is used as a refinery fuel without ever being seen. Marketable petroleum coke is the final "bottom-of-the-barrel" product of the oil refinery process. Marketable coke may be raw or green coke, or it may be calcined; that is, put through a roasting process in the presence of a flame to drive out the volatile impurities. There are three main outlets for marketable petroleum cokes: (1) Use as fuel, (2) manufacture of carbon products such as electrodes for metallurgical furnaces and silicon carbide abrasives, and (3) export.

Petroleum coke production totaled 123,746,000 barrels in 1974, a 6.4% decrease from that of 1973. Nearly 52%, or 63,950,000 barrels was marketable coke, as shown in table 39. Exports of marketable coke, rose almost 18% to 41,244,000 barrels. Nearly 30% of exports (12,344,000 barrels) went to Japan, an increase of 34% over the 9,197,000 shipped in 1973. Canada participated in the increase, receiving 5,185,000 barrels, a 25% increase. Conversely, exports to Europe were 9.6% lower; shipments to Belgium, Italy, the United Kingdom, and West Germany decreased. Volumewise, petroleum coke is our largest petroleum product export (table 59); it accounted for 51% of the 80,491,000 barrels exported in 1974.

Asphalt and Road Oil.—As a result of a slackening in road construction and building activity, asphalt and asphaltic products shipments in the United States in 1974 declined 7% from 34.3 million tons (5.5 barrels=1 short ton) to 31.8 million tons.

Shipments of petroleum asphalt paving products were 25.4 million tons, 1.7 million tons below those of 1973, as shown in table 40. Likewise, shipments of asphalt roofing products declined 11% from 5.7 million tons. Production of asphalt also declined moderately from 30.5 million to 29.9 million tons. With demand down, stocks rose slightly in 1974 (table 41).

[7] U.S. Code of Federal Regulations. Federal Energy Guidelines, Part 211, Subpart 211.61. Federal Energy Administration, Washington, D.C.

[8] U.S. Bureau of Mines. Crude Petroleum, Petroleum Products, and Natural Gas Liquids. Mineral Industry Survey, April 1975 issue, released Aug. 8, 1975, 30 pp.

Shipments of road oil in 1974 totaled 1,251,091 tons, or 12% less than in 1973, as shown in table 42. Production declined slightly, but with demand reduced, inventories were restored in 1974. Trends in demand for asphalt and road oil over 1970–74 are indicated in table 40. Comparisons for 1973 and 1974 are also shown in tables 41 and 42 and are presented in the Bureau of Mines Mineral Industry Survey.[9]

Miscellaneous Finished Oils.—The petroleum industry produces a variety of miscellaneous products that are sold directly to consumers or in bulk to specialty companies, which package and distribute them under various trade names. Included in this category would be absorption oils, specialty oils such as hydraulic and insulating oils, medicinal oils, rust preventives, sand face, spray oils, and others. Also, SNG feedstock is included in this grouping. Production aggregated 25,246,000 barrels, a 27% gain over that of 1973. Most of the increase was in the petrochemicals category, as indicated in table 43.

Unfinished Oils.—Unfinished oils are oils that have been partly refined and will be further processed by refiners; examples are unfinished naphtha, gas oil, virgin- or straight-run naphtha, topped crude, cracking stock, etc. The rerun (net of unfinished oils) represents the receipts of domestic or foreign oil plus or minus changes in stocks.

TRANSPORTATION AND DISTRIBUTION

CRUDE OIL

A transportation system comprised of pipelines, tankers, barges, tank cars and, to a lesser degree, tank trucks move crude petroleum to refineries for processing. Refineries received 70.4% of their crude oil requirements by pipeline, 27.9% by water, and 1.7% by tank cars and trucks in 1974.

The 17 States comprising PAD district I accounted for 37.1% of domestic product demand. However, refineries in district I supplied only 17% of that demand. Foreign crude oil made up the lion's share, 83% of refinery input in district I; 14% came from other districts, and 3% came from within the district.

Tankers and barge movements of crude oil and petroleum products from the gulf coast to the east coast is shown in table 46.

Refined products produced at refineries in PAD district V in 1974 represented 90% of the domestic product demand for that district. Crude oil produced in district V supplied 57% of refinery input, foreign crude oil supplied 41%, and 2% was received from other PAD districts.

Data collected on receipts of domestic and foreign crude petroleum at refineries in the United States show receipts from local production (intrastate), receipts from other States (interstate), and receipts of imported crude. These data, by method of transportation, indicate the final receipts by water, pipeline, tank car, and truck. Receipts of domestic crude by water usually are moved by pipeline from the point of production to the point of water shipment.

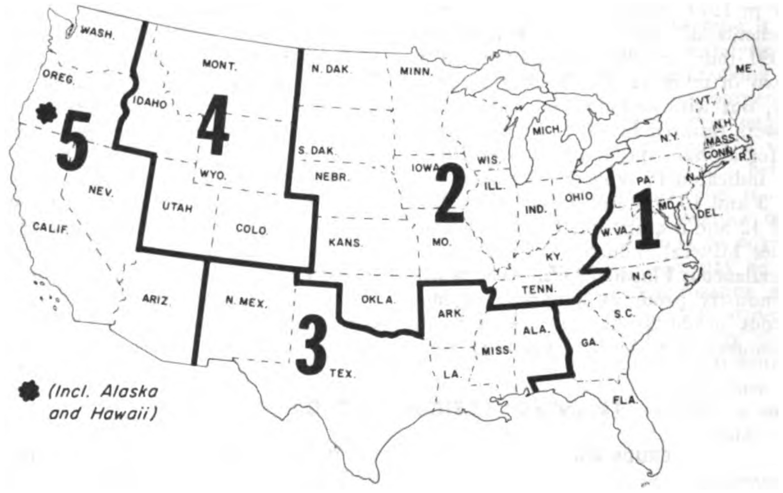
PETROLEUM ADMINISTRATION FOR DEFENSE (PAD) DISTRICTS



BUREAU OF MINES REFINING DISTRICTS

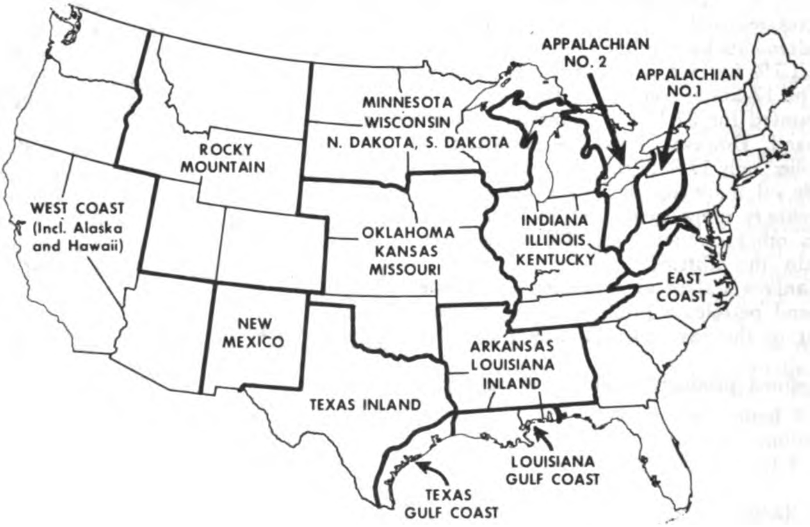


Figure 5.—Maps of Petroleum Administration for Defense (PAD) districts and Bureau of Mines refining districts.

Refinery receipts of crude oil carried by tankers and barges totaled 1,238 million barrels, or nearly 3.4 million bpd, in 1974. In 1973, 1,174.0 million barrels, or 3.2 million bpd, were received by refineries. About 896 million barrels (2,455,200 bpd) represented refinery receipts of foreign crude in 1974; the comparable figure in 1973 was 775 million barrels, or 2,124,200 bpd. A 5 year series of receipts is shown in table 44, interdistrict movements by tanker and barge are provided by tables 45 and 46.

REFINED PRODUCTS

Domestic demand for petroleum products averaged 16.6 million bpd in 1974, a 3.9% drop from the 17.3 million bpd of 1973. Demand in 1974 is broken down by PAD districts in table 14.

PIPELINES

The Bureau of Mines triennial pipeline survey of January 1, 1974, reported that pipeline mileage on that date totaled 222,355 compared with 218,671 miles as of January 1, 1971. Crude oil trunklines accounted for 76,250 miles, which is a nominal increase over the mileage reported as of January 1, 1971. Crude oil gathering lines mileage continued to decline, dropping 2.6% to a January 1, 1974, level of 69,260 miles; mileage had reached a peak of 76,988 in 1962. Capacity of crude oil trunklines increased to 71,159,000 barrels, a slight gain over that of 1971. However, product lines capacity increased 15% to 48,775,000 barrels. Part of this increase resulted from replacement of existing lines with larger diameter pipe; part represented new mileage. It is estimated that 598 miles of crude oil lines were laid in 1973 compared with 361 miles in 1972.

Crude oil pipelines delivered 3,124.6 million barrels or 8,560,000 bpd to refineries in 1974, a decrease of 5.7% from the 9,078,000 bpd in 1973 (table 44). Petroleum product pipelines delivered 3,204.9 million barrels, or an average of 8,780,000 bpd in 1973, compared with 2,967.9 million barrels, or 8,109,000 bpd, in 1972. Transportation by pipeline of petroleum products between PAD districts is shown in table 47. Transportation and stocks in lines and working tanks is available in table 48; tariff rates, table 49.

RAIL, TANK TRUCK, BARGE AND TANKERS

The annual survey of the Association of Oil pipelines estimated that the total tonnage of crude oil and petroleum products carried was 1.9 billion tons in 1973. Of this total, 47.44% was transported by pipelines, 21.90% by water carriers, 29.11% by motor carriers, and 1.55% by railroads. On an overall basis, volumes transported in 1973 were 4% greater than those in 1972. Petroleum products accounted for 66% of the volume transported.

Product pipelines transport only the light products such as gasoline, light fuel oils, and heating oils, LPG, kerosine, and jet fuel. These lines transported 1,282,527,200 tons, or 32.74%, of the total. Motor carriers transported 504,177,000, or 39.31%, of the petroleum products carried. In terms of billions of ton miles, the total aggregated 478.0, of which 42.9% was transported by pipelines, 49.8% by water carriers, 4.9% by motor carriers, and 2.4% by railroads. Total crude petroleum carried in domestic transportation, in billions of ton miles, was 362.9 in 1973. Pipelines accounted for 83.2% and water carriers for 16.2%.

Deepwater Ports.—Many of the tankers in use today are very large crude carriers (VLCC's) and virtually all of these ships are unable to enter ports with a depth under 75 feet. At the present time, there are no ports in the United States capable of accommodating VLCC's with capacities greater than 200,000 deadweight tons. The deepest ports in the United States are located on the west coast and can handle only tankers up to 150,000 deadweight tons. Most harbors in the United States are limited to smaller ships with capacities ranging from 40,000 to 70,000 deadweight tons. Hence, the need for deepwater ports has become imperative.

The Deepwater Port Act of 1974, signed by the President, provided for licensing and regulation of deepwater ports. The Secretary of Transportation is empowered to grant licenses for ownership, construction, and operation of deepwater-port facilities. At the same time, a Governor of an adjacent coastal State located within 15 miles of a deepwater port or connected directly by pipeline, to a deepwater port could veto the project.

Two corporations, formed by groups of companies, are planning to construct two such ports: One off the Louisiana coast in water over 100 feet deep in the Gulf of Mexico, and the other off the Texas coast. In the Louisiana Offshore Oil Port (LOOP), the corporation proposes to store imported oil in the Clovelly salt dome near Galliano, La. The proposed storage capacity of this facility is expected to be about 56 million barrels of oil.

TANKER RATES

Tanker charter rates, after reaching a peak late in 1973, have been in a downtrend. From $2.02 per barrel, charters in December 1973 for 34 degree crude oil for Large Range 2 tankers (from 80,000 to 159,999 deadweight tons (dwt)) dropped nearly 40% by December 1974 to $1.21 per barrel, for cargoes destined from Ras Tanura to New York via the Cape of Good Hope. Charters, same destination, for vessels of 16,000 to 24,999 dwt, which are classified as "General Purpose" tankers, dropped over the same 1973-74 interval from $3.23 per barrel to $2.63 per barrel.

This softening in rates is readily understandable. Consumer resistance to higher prices for crude oil and products, a mild winter, intensive conservation programs, and the economic recession resulted in a 3.6% drop in 1974 demand. Moreover, an oversaturation in tanker supply has helped to weaken tanker rates and there was little evidence of a change in that situation in 1975. It should be noted, however, that average tanker charter rates move slowly since they include charters, which run about 3 years. Also, much of the shipping moves in company-owned vessels.

STOCKS

Stocks of all oils have been increasing steadily after touching a low point of 866.9 million barrels in February 1973. This was the lowest inventory position since February 1968, and close to stock levels during the 1967 Arab-Israeli conflict, which cut off imports from the Mideast. By the end of 1974, stocks of all oils had recovered to 1,073.6 million barrels, an increase of 65.3 million barrels over the inventory position at the end of 1973 as shown in table 50. Stocks of refined products were 36.2 million barrels higher at yearend 1974. Crude oil stocks, which shrank from 279.5 million barrels in May 1972 to a 7-year low of 235.4 million barrels in February 1973, recovered at least in part to 265 million barrels by the end of 1974 as imports increased. The stock position continued to strengthen in 1975.

PRICES

Crude Oil.—The increase of the host countries shares in oil participations from 25% to 60%, the embargo of oil shipments to the United States by Arab nations, and the sharp increases in prices adopted by the Organization of Petroleum Exporting Countries (OPEC) have all contributed to the price increases that caused consternation in the oil-consuming nations throughout the world in 1973 and into 1974. The uptrend continued in 1974, but with economic recession worldwide and crude oil a glut on world markets, the climb in prices had been arrested as of mid-1975.

By way of background, a large part of crude oil obtained from foreign countries was equity oil; that is, oil produced and owned by companies that had obtained concessions from host countries and/or governments. In return, the companies were required to pay both a royalty and tax for oil produced. The aggregate of tax royalty and the cost to produce oil represented the total cost of equity oil and was termed "tax-paid cost." The royalty and tax were based on a posted price that was initially established by negotiations between the host country and the oil-producing company. More recently, however, the host government alone establishes the posted price.

In January 1973, Saudi Arabia, the United Arab Emirates, and Qatar adopted participation agreements which gave those governments 25% ownership of the oil produced in their respective countries. This 25% segment was known as "participation oil" and most of this oil was sold back to the producing companies at "buyback prices." As a result, oil prices rose as the higher priced "buyback" oil was averaged in with equity oil. Subsequently, the host governments increased their participation from 25% to 60%. Some countries also raised the tax rate and the royalty.

Prices continued to rise in 1974, and the uptrend continued into 1975. The posted price for Arabian light crude oil as of January 1974 was $11.65 per barrel. This price was equivalent to an average equity and buyback cost of $9.27 per barrel.

On the domestic scene, the average price of crude oil at the wellhead, which was $3.39 per barrel in 1971, held at that level through 1972. However, in March 1973, the Cost of Living Council (CLC) granted an increase of $0.25 per barrel, lifting the price to $3.64 per barrel. On May 15, 1973, the CLC allowed another $0.35 increase. Under phase 4 petroleum regulations, the ceiling price for crude oil was the posted price in each U.S. oilfield plus $0.35 per barrel. The average value per barrel at wells was $6.74, or 73% above the $3.89 per barrel of 1973, as shown in table 55.

On August 17, 1973, in an effort to stimulate production of domestic crude oil, the CLC enacted a two-tier pricing system under phase 4 oil regulations. The system released from ceiling prices "new oil" (oil produced above 1972 levels) and made an adjustment for the remainder of current production. The price of new oil produced, which was not covered by the price ceiling, rose steadily to market levels. The ceiling price for domestic crude was about $1 per barrel below the world price at the time phase 4 rules were issued on August 17. Since then, however, world prices have increased sharply and so have prices for new or exempt oil; that is, oil exempt from price controls. What constituted exempt oil was broadened as of November 16, 1973, when the CLC exempted prices charged for the first sale of crude petroleum and petroleum condensates, including natural gas liquids produced from any stripper-well lease. A "stripper-well lease" was defined as a property whose average daily production of crude petroleum, condensates, etc., did not exceed 10 bpd during the preceding calendar month.

The price-regulating function of CLC was absorbed by FEA in March 1974, and FEA took over this work in May 1974.

Between September and the end of December 1973, the price of new or exempt oil rose from $5.12 to $9.51 per barrel. Between January 1974 and December 1974, the price per barrel rose 13% from $9.82 or $11.08. The price of old or controlled oil rose nearly 35% from $3.90 per barrel in August 1973 to $5.25 in December. The $5.25 price prevailed through 1974 and carried over into 1975.

In spite of price controls, petroleum prices have climbed steadily and so have prices refiners must pay for crude oil, both domestic and foreign (refiner's acquisition costs). The following tabulation shows refiner's acquisition cost per barrel for imported oil, domestic oil, and a composite of both, as maintained by FEA:

	Domestic	Imported	Composite
1973:			
May	$3.82	$3.92	$3.85
November	5.00	6.49	5.45
December	5.95	8.22	6.54
1974:			
January	6.72	9.59	7.46
April	7.21	12.72	9.18
July	7.19	12.75	9.30
October	7.26	12.44	9.22
December	7.39	12.82	9.28
1975:			
January	7.78	12.77	9.48
April	8.23	13.26	9.83
May	8.33	13.27	9.79
June	[1] 8.33	14.15	[1] 10.23

[1] Preliminary.

As shown in the tabulation, a composite of refiners' acquisition costs of imported and domestic crude was $3.85 per barrel in May 1973. By April 1975, the price was $9.83 per barrel, or more than 2½ times greater. The rise was due primarily to the increase in the cost of imported oil. The refiner's acquisition cost for imported oil rose from $3.92 per barrel in May 1973 to $13.26 per barrel by March 1975, better than a threefold increase.

Likewise, the price of domestic oil climbed steadily after enactment of the two-tier price system.

Entitlements.—Subsequent to adoption of the two-tier pricing system, FEA in November 1974 initiated the entitlements system under the Old Oil Allocation Program (CFR 211.67). Every refiner had to have an entitlement to process a barrel of old crude oil as a percentage of total crude processed (that is, the total runs to stills) of old oil, imported oil, and domestic exempted oil. Each month, FEA calculates the amount of old oil produced as a percentage of total crude oil processed. If, for example, the old-oil ratio was 40% and a refiner's old-oil ratio was 60%, this refiner would have to buy entitlements equal to 20% at prices set by FEA from those refiners with less than 40%. An entitlement purchased at $5.00 would entitle the purchaser to process 1 barrel of old oil at about $5.25 per barrel, so that the effective cost would be about $10.25 per barrel for the 20% over the old-oil ratio.

Refined Products.—Price controls on refined products were eased under phase 4 to permit refiners to pass through at least part of the increased costs. These refiner's acquisition costs are ultimately passed through to the consumer in higher prices for petroleum products such as gasoline, home-heating fuel oil, and diesel fuels. Data on prices of selected crude oils and products are available in tables 56–58.

In the United States, gasoline outweighs all other products in terms of volume produced and relative importance in the refinery mix. Prices of gasoline in 1973 did not begin to rise until after OPEC action on crude oil in October 1973, but from then on the climb was rapid. The average service station price of regular-grade gasoline (including taxes) was 38.71 cents per gallon as of September 1, 1973. By December 1, the price had risen to 42.26 cents. Prices have continued upward. By December 1, 1974, the price was 53.15 cents, according to Platt's Oil Price Handbook and Oilmanac 1974.

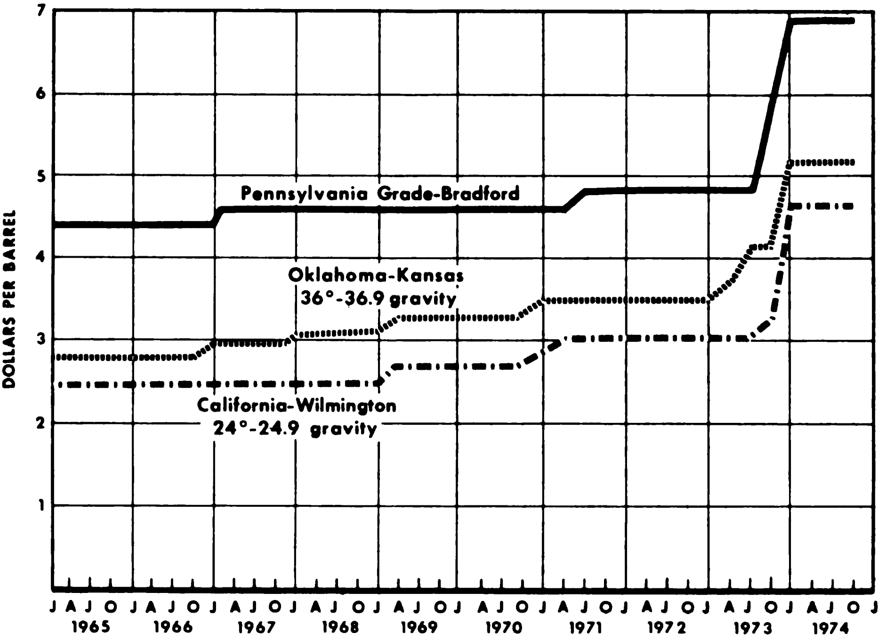

Figure 6.—Posted prices of selected grades of crude petroleum.

Shown in the following tabulation (in dollars per 100 gallons) are some comparisons in selected cities of prices of No. 2 home-heating oil between 1972 and January 1975. These intervals indicate the impact of the pass-through policy on retail prices. Between January 1974 and January 1975, the U.S. average rose 15%.

Standard metropolitan statistical areas	December 1972	December 1973	January 1974	January 1975
U.S. average	$19.72	$22.75	$32.89	$37.84
Baltimore	19.33	26.64	31.18	36.60
Boston	20.40	30.44	32.90	40.06
Chicago and Northwestern Indiana	18.66	27.01	31.66	38.96
Detroit	18.62	25.14	30.35	35.76
Milwaukee	18.93	27.85	31.23	36.58
Minneapolis-St. Paul	18.06	26.42	34.74	35.72
New York and Northeastern New Jersey	20.40	33.41	36.90	40.04
Philadelphia	19.23	26.27	31.30	37.96
St. Louis	19.49	26.53	33.72	37.51
Washington, D.C	19.78	29.95	33.30	40.82
Seattle	22.17	27.28	33.50	38.20

Source: Bureau of Labor Statistics.

Residual Fuel Oil Prices.—The price of Bunker "C" fuel oil at New York Harbor was depressed throughout 1972, but demand for tankers quickened and fuel oil prices stiffened. From $3.45 per barrel at the end of 1972, prices for Bunker "C" climbed steadily to $5.42 per barrel by December 1973. By December 1974, the price had more than doubled to $11.09 per barrel. The trend of Bunker "C" prices for 1964–74 inclusive, is shown in figure 7.

Unlike Bunker "C" fuel, use of No. 6 residual fuel oil is restricted to 0.3% sulfur in many communities along the eastern seaboard. New York City is an example. The average price per barrel for No. 6 fuel oil in New York Harbor market since 1971 was as follows:

1971	$4.87
1972	4.66
1973	5.99
1974	14.11
1975 (January 2)	12.55

The softening in the January 1975 price reflects, in part, the mild winter and the decline in business activity.

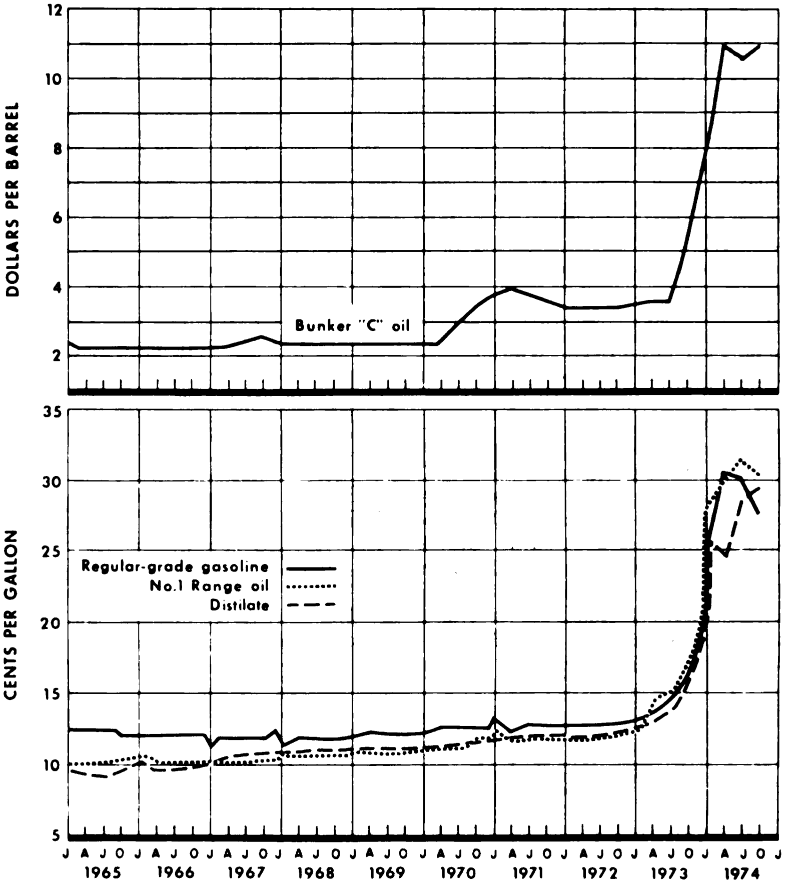

Figure 7.—Quarterly prices of Bunker "C" and No. 2 distillate fuel at New York Harbor, No. 1 range oil at Chicago district, and regular-grade gasoline at refineries in Oklahoma.

FOREIGN TRADE

Exports.—Exports of refined products and crude oil in 1974 were down 3.9 million barrels; the 6.3-million-barrel increase in petroleum coke exports was more than offset by declines in exports of distillate, petrochemical feedstocks, gasoline, lubricating oil, naphtha, and jet fuel. Coke accounted for 51% of exports. Japan overshadowed all other countries in accounting for 12.3 million barrels, or 30%, of petroleum coke sales in terms of volume. Canada was second in importance with 12.6%. Exports by product and destination in 1973 and 1974 are shown in table 60.

Imports.—Imports of crude oil and refined products aggregated 2,222.2 million barrels, or 6.1 million bpd, in 1974, a decrease of 2.7%. An increase in crude imports failed to offset the 13% drop in imports of products. The Arab oil embargo ended toward the end of the 1974 first quarter, and by yearend, crude imports totaled 1,269 million barrels or 3.48 million bpd, 7% over 1973 imports as shown in table 61. The sharpest increases in imports were from Iran, Nigeria, and Indonesia. As a result of Canada's planned cutback in crude oil exports to the United

States, imports from that country fell from 1 million bpd to about 791,000 bpd. Despite these cutbacks, more oil was imported from Canada in 1974 than any other country as shown in table 62.

Nigeria was the second largest supplier of crude oil to the United States. Imports from that country averaged nearly 697,000 bpd in 1974, a 55% increase over the amount received in 1973. Imports from Africa in 1974 were nearly as large as those from the Middle East.

Imports of refined products in 1974 aggregated 2.6 million bpd, 13% less than the 3.0 million bpd in 1973. Most of the decrease was in residual fuel oil, distillate fuel oil, and kerosine-type jet fuel; imports were lower by 433,000 bpd. Gasoline imports were 25.6 million barrels, or 52.6%, higher than in 1973. Most of these increases originated in Europe, South America, and Central America. Comparisons of imports in 1974 and 1973 by country and product are shown in table 62.

Included in the totals for imports of refined products were 1,783,000 barrels of naphtha-type jet fuel, 32,701,000 barrels of kerosine-type jet fuel, 3,967,000 barrels of distillate, and 34,710,000 barrels of residual fuel oil, all of which were withdrawn from bond for use as fuel for aircraft and vessels engaged in overseas commerce. These imports were exempted from tariff duties. Residual fuel oil imported by the military for offshore use in 1974 totaled 2,879,000 barrels, 14% less than the volume used in 1973.

NATIVE ASPHALT

Bituminous Limestone, Sandstone, and Gilsonite.—Natural rock asphalt and limestone rock asphalt were produced in Alabama, Missouri, and Texas, and were used for road-building material. Gilsonite was produced in Utah. The total production of native asphalts and related bitumens in 1974 was 2,021,165 tons with a value of $16,666,000.

WORLD REVIEW

The petroleum production cutbacks and the embargoes against deliveries to select market-economy nations adopted as a political weapon by Arab interests at the outbreak of Arab-Israeli hostilities, had been relaxed and eventually withdrawn by the spring of 1974. However, the fourfold increase in the price of Arabian light "marker" crude at $11.65 per barrel, effected by the 13 member nations of OPEC resulted in economic crisis in the major industrial countries as higher costs further inflated economies and stagnated industries. Developing nations were equally threatened since their foreign exchange reserves could not absorb higher energy prices, which placed their economic development in jeopardy. Participation agreements between state-owned companies and foreign operations increased in favor of the state. Nationalization of petroleum operations was realized in Algeria, Iraq, Iran, Libya, and Nigeria and was pending in Kuwait, Venezuela and Saudi Arabia. Both these factors disrupted normal trading relations and traditional supply sources, adding to the mounting problems of oil-consuming nations.

In mid-November, the International Energy Agency, representing 17 oil-consuming nations, was formed to share energy resources in the event of another embargo and to promote international cooperation in the development of alternative energy sources. In 1974, imported petroleum accounted for more than 60% of the primary energy source of Western Europe, 80% of the primary energy source of Japan, and nearly 17% of the primary energy source of the United States. The development of alternative energy sources for major oil importing areas had met with little progress by yearend, principally because of the vast expenditures required to launch such a program. Alternative energy expenditures that may be justified at a marker price of $11.65 per barrel of imported oil may not be justified if the price of imported oil is reduced. Because the current posted price expresses between 50 to 100 times the actual cost of producing Middle East oil, price reductions in a competitive market are a possible threat to high-cost alternative-energy development. However, this possibility appears remote in light of the mid-November OPEC meeting in Vienna advocating even higher prices for imported oil.

Production.—World crude oil production in 1974 averaged 56.3 million bpd, including an estimated 9.0 million bpd recovered from offshore operations. Production results for 1974 reflected an increase of less than 1% over that of 1973. This represented a sharp decline in the 7% to 10% annual growth rate historically achieved in the production of petroleum, as shown in table 63. During the year, ranking producers were realigned, bringing the U.S.S.R. to first position in crude oil production, followed by the United States, Saudi Arabia, and Iran.

Substantial production increases above 1973 production levels were reported by the following countries: Saudi Arabia, nearly 885,000 bpd; the U.S.S.R., approximately 765,000 bpd; and the People's Republic of China, averaging about 300,000 bpd. These increases were largely counterbalanced by significant production declines in the following countries: Libya, more than 650,000 bpd; Kuwait, nearly 475,000 bpd; the United States, nearly 435,000 bpd; and Venezuela, nearly 390,000 bpd.

Crude oil production by member nations of OPEC declined more than 300,000 bpd from 1973 production levels; however, the 13 nations constituting the OPEC group continued to account for about 55% of total world crude oil production. Production declines registered by the North African and South American member nations were largely offset by increased production from member nations in the Middle East. Member nations of OPEC in the Middle East are Saudi Arabia, Iran, Kuwait, Iraq, United Arab Emirates, and Qatar. Combined production from these members totaled nearly 21.2 million bpd compared with 20.6 million bpd in 1973.

Crude Oil Movements.—During 1974, crude oil movements to the major consuming centers of Western Europe, Japan, and the United States totaled nearly 22 million bpd; the Middle East supplied 65% of the total (figure 8). Approximately 13.7 million bpd was imported by Western Europe, which represented a decline of nearly 1 million bpd from the 1973 import levels (when prices were lower).

Japanese crude oil imports averaged 4.8 million bpd, a decline of 100,000 bpd from that of 1973. Although imports from the Middle East supplied 77% of Japanese total crude oil imports in 1974, the flow of Middle East crude was reduced by 125,000 bpd, compared with 1973 imports. However, Japanese crude imports from the People's Republic of China have nearly quadrupled in this period.

The United States imported nearly 3.5 million bpd of crude oil. Canada supplied nearly 791,000 bpd; Nigeria supplied nearly 700,000 bpd; Iran 463,000 and Saudi Arabia supplied about 438,000 bpd.

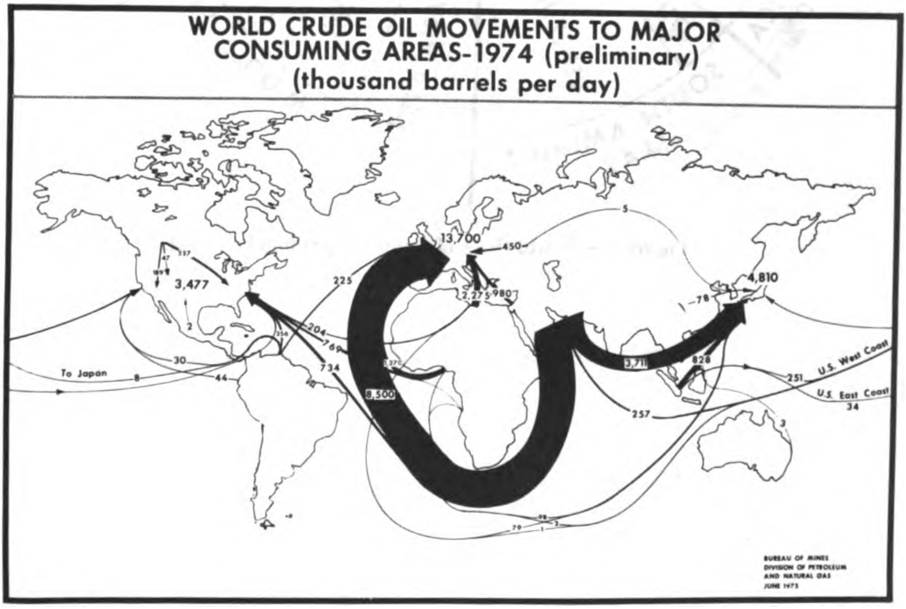

Figure 8.—World crude oil movements to major consuming areas, 1974.

1964 - 10.3 BILLION BARRELS

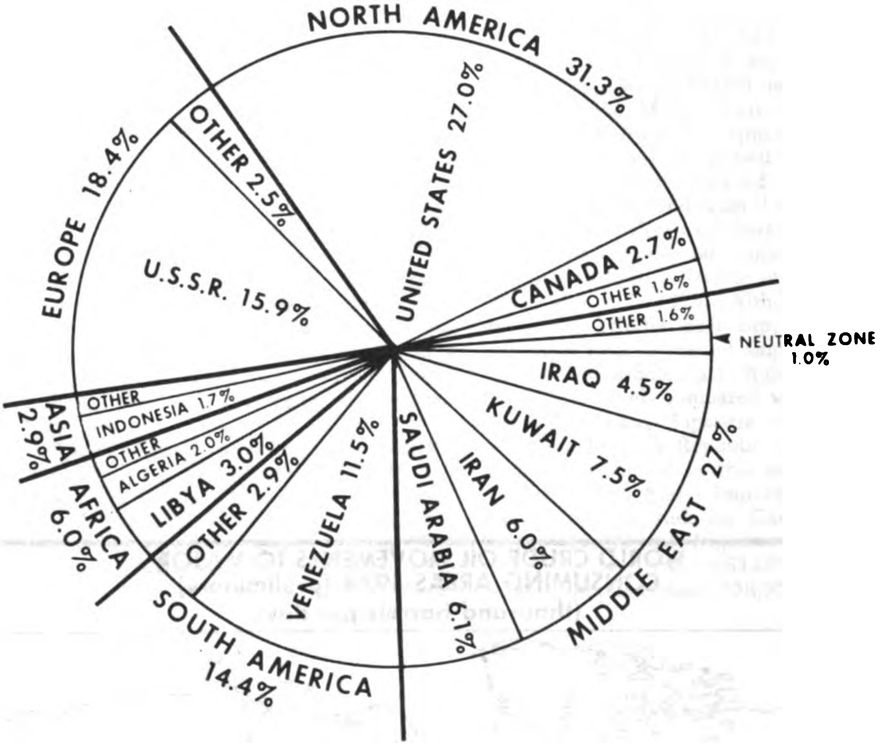

Figure 9.—World share of crude oil production, 1964.

1974 - 20.5 BILLION BARRELS

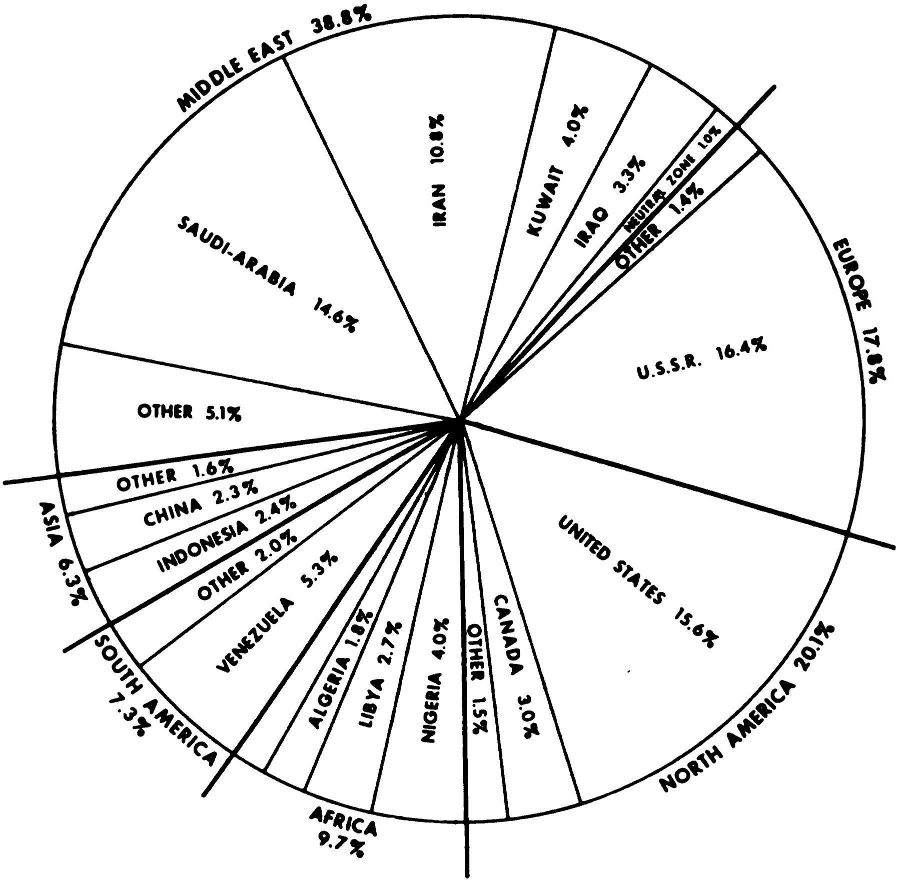

Figure 10.—World share of crude oil production, 1974.

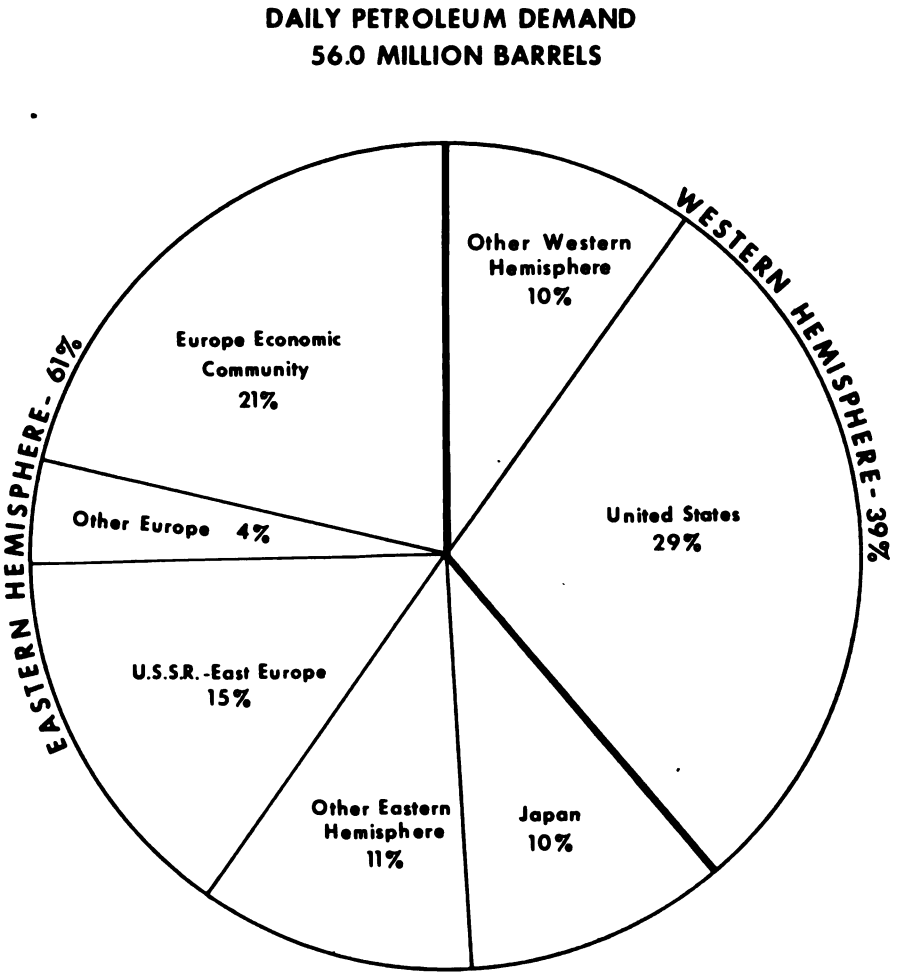

Figure 11.—World daily petroleum demand, 1974.

Transportation.—Excluding about 42 million dwt in combined carriers, the world tanker fleet at yearend 1974 totaled 260 million dwt, an increase of 40 million dwt over that of 1973. The decline in world petroleum consumption with the resulting drop in demand for tanker transportation created a tanker surplus nearly equivalent to the additional capacity added in 1974.

About 30% of total tanker tonnage sails under the Liberian flag, followed by registries in the United Kingdom and Japan, which account for 13% and 11%, respectively. Tankers between 200,000- and 285,000-dwt capacity constitute more than 40% of the total tanker fleet. Most of the additional tanker capacity available in 1974 was in this category.

Voyages from the Middle East occupied an estimated 77% of the oceangoing fleet. Although voyages from the Middle East to Europe and Japan were slightly reduced, they continued to occupy nearly 60% of the total oceangoing fleet.

At yearend, vessels carrying LPG numbered 431, with a total carrying capacity of 4 million cubic meters, or nearly 141.3 million cubic feet.

Refining Capacity.—Total world crude oil refining capacity at yearend was estimated at 65.5 million bpd, an increase of less than 1 million bpd over 1973 capacity levels. The Eastern Hemisphere, containing the major refining centers of Western Europe, the U.S.S.R., and Japan, accounted for 64% of total world refining capacity, or approximately 42 million bpd. Currently scheduled expansion and construction programs should increase world refining capacity to an estimated 90 million bpd by 1978; however, reduced consumption trends may require reappraisal of refinery expansion plans, particularly in Western Europe and Japan.

Consumption.—World petroleum consumption declined to an estimated level of 55.4 million bpd in 1974 as a result of the fourfold increase in petroleum pricing. Consumption levels in major industrial areas were markedly reduced. Western European consumption was reduced by well over 1 million bpd. Japanese consumption was reduced by 120,000 bpd.

Algeria.—Crude reserves were estimated at nearly 8 billion barrels. To augment these reserves, the state-owned company Société Nationale pour la Recherche, la Production, le Transport, la Transformation, et la Commercialisation des Hydrocarbures (SONATRACH) has engaged in multiple exploration agreements with leading French, West German, Spanish, and United States firms. During the year, at least nine firms entered 49% to 51% joint venture arrangements with SONATRACH. Foreign exploration partners bear exploration costs and, in the event of discovery, SONATRACH reimburses up to 15% of exploration costs and assumes 51% of all development cost.

Economic development plans include expansion of petroleum production from 1 million bpd in 1974 to 1.5 million bpd in 1980, and the expansion of refining capacity from 115,000 bpd to 600,000 bpd in the same time period.

The Italian firm Società Nazionale Metanodotti Progetti S.p.A. (SNAM) is construction contractor for a 300,000-bpd-capacity refinery at Skikda. The refinery yield will serve both the export market and the Algerian petrochemical industry.

Argentina.—By a July decree, the state-owned Yacimientos Petrolíferos Fiscales (YPF) took over control of marketing operations of Esso Corp., Cities Service Co., Royal Dutch/Shell, and four smaller companies, thus controlling all gasoline sales in the country. During the year, the Argentinian congress was deliberating on the hydrocarbons law, which affords YPF control over all petroleum operations in the country. Production in 1974 averaged 414,000 bpd. Domestic and imported crude oils (principally from Libya) were refined in 14 refineries with a combined capacity of 720,000 bpd. Petroleum consumption was estimated at 500,000 bpd; more than 25% was derived from imported crude oil and products.

A 32-inch-diameter, 240,000-bpd-capacity pipeline was completed between Puerto Rosales and the 290,000-bpd-capacity La Plata refinery, cutting the cost of crude oil delivered via waters too shallow to accommodate large tankers.

Australia.—Legislation placing control of the petroleum industry under the Federal Government was under review by the High Court. Two laws were under review: The Petroleum and Minerals Authority Act, which establishes a Government agency for exploration, production and marketing petroleum; and the Seas and Submerged Lands Act, which transfers jurisdiction over offshore operations from States to the Federal Government. Approximately 115,-

800 square miles of exploration leases will expire or come up for renewal in 1974–75. The Government has announced its intention to take over these leases, eventually maintaining at least 50% equity with private operating groups.

Offshore operations in the Bass Strait yielded an average of nearly 360,000 bpd of crude oil, accounting for the bulk of Australia's production. The Mackerel field, with reserves of 200 million barrels, and the Tuna field, with reserves of 84 million barrels, will enter the Bass Strait production network in 1977 and 1978 respectively.

Austria.—Austrian production averaged nearly 43,000 bpd. The Austrian national company, Österreichische Mineral-ölverwaltung A.G. (ÖMV), accounted for the bulk of output, producing 38,000 bpd. Domestic and imported crude is refined at the 220,000-bpd-capacity ÖMV Schwechat refinery. Consumption of petroleum products was reported at 210,000 bpd, a 10.2% reduction from consumption levels in 1973 and a reversal of the 9.3% annual average rate of increase experienced in 1969–73. Major consumption declines were reported for lubricants, kerosine, special gasoline, distillate fuel oil, and residual fuels.

Bahamas.—Bahamas Oil Refining Co. at Freeport operated a 500,000-bpd-capacity refinery on imported crude oils. Construction of two additional refineries are under consideration; these include a 250,000 to 300,000-bpd-capacity refinery near Pelican Point, and a 125,000 to 250,000-bpd-capacity refinery on Grand Bahama Island.

Brazil.—Petroleum imports averaging 600,000 bpd satisfied about 80% of Brazil's petroleum consumption requirements. In 1974, petroleum imports placed a $3 billion drain in the national balance of payments position. In an effort to reduce the outflow of Brazilian capital, the state-owned Petróleo Brasileira S.A. (PETROBRAS) accelerated exploration activities along the continental shelf where at least three promising discoveries were reported in 1974. Most significant of these is the Garoupa field discovered just offshore of Rio de Janeiro. Probable reserve estimates are 600 million barrels of crude oil, testing at 31° API gravity with 0.14% sulfur content.

In addition to accelerated exploration and development activity, Brazil has awarded contracts to SNAM of Italy and the Japan Gasoline Co. to participate in refinery construction and expansion, which will raise refining capacity from 962,000 bpd in 1974 to 1.3 million bpd by 1978.

China, People's Republic of.—Output continued to climb, increasing 30% over 1973 output to a production level averaging 1.3 million bpd. Much of China's crude oil is derived from the north and northeast provinces, which include the Taching Field.

Refining capacity has historically balanced crude oil production capacity; however, recent drilling and field development have escalated China's crude oil production beyond refining capacity, and increased crude oil exports are anticipated for the immediate future. To facilitate crude oil exports, a pipeline connecting Taching Field with the Pohai Bay port of Dairen was under construction in 1974.

Indonesia.—Extensive exploration activity resulted in the addition of 5 billion barrels to Indonesia's petroleum reserves, raising the total to 15 billion barrels as of December 31, 1974. During the year, 231 exploratory wells were completed, resulting in 71 discovery wells and a success ratio of nearly 1:3. Major discoveries were reported by Phillips Petroleum Co. operating in the Teluk Berou area, by Atlantic Richfield Indonesia Ltd. operating in the Ardjuna area, by the Indonesian-American Oil Co. operating in the Java Sea (south of Sumatra), and by the Union Oil Co. operating in the Straits of Macassar (east of Kalimantan).

Crude production averaged 1.37 million bpd in 1974, a slight increase over the 1973 production level. During the first half of the year, production averaged 1.5 million bpd, but as a result of reduced demand, production declined to an average of 1.2 million bpd for the remainder of the year.

More than 75% of Indonesia's crude oil is exported, with Japan and the United States the principal markets. Although a member of OPEC, Indonesia prices crude oil above the Arabian light marker crude oil price. Indonesian light crude oil buyers pay a low-sulfur premium, and Pacific area buyers pay a freight differential on Indonesian crude oil. The sales price for 34° API gravity crude oil was $10.80 per barrel on January 1, 1974, was raised to $12.60 on July 1, and remained at that level through the year in spite of reduced demand.

Iran.—Production averaged more than 6 million bpd with the Marun, Agha Jari, Gachsaran, and Ahwaz fields each averaging nearly 1 million bpd or more. Iran anticipates production levels averaging 7.5 million bpd by 1977 as a result of a vast gas-injection program.

Iran exports well over 5 million barrels of crude oil per day. The economic advantage realized from the export of petroleum products has prompted Iran to engage in negotiations for construction of several export refineries of 500,000-bpd capacity. During 1974, negotiations centered on two proposed export refineries involving the partnership of the National Iranian Oil Co. (NIOC) with several West German interests in the construction of a 500,000-bpd-capacity refinery at Bushire, as well as a partnership involving NIOC and Royal Dutch/Shell in a second refinery of similar size at an undetermined location. No firm construction contracts for export refineries were announced by yearend.

Saudi Arabia.—Maintaining the position of third largest world producer of crude oil, Saudi Arabia produced an average of 8.5 million bpd of crude oil in 1974. More than 4.6 million barrels was produced from the Ghawar field, whereas the Safaniyah offshore field produced well over 1 million barrels, and the Berri offshore field produced nearly 0.9 million bpd.

The Saudi Arabian Government acquired 25% participation in the Arabian American Oil Co. (Aramco) in 1973. By 1974, Government participation was increased to 60%, with negotiations underway for a full Government takeover.

U.S.S.R.—Production of crude oil and field condensate averaged 9.2 million bpd, affording the U.S.S.R. the lead position among world crude oil producers. The 9% increase over 1973 production was largely attributed to development of the West Siberian fields, the largest of which is Samotlar, where production exceeded 1.2 million bpd in 1974. Total production from West Siberia reached 2.34 million bpd in 1974. Total Soviet crude production was expected to reach 9.8 million bpd by 1975. West Siberia will account for nearly one-third of the output, with the Samotlar field alone producing 1.8 million bpd.

Approximately 80 refineries with an estimated combined capacity of 7.3 million bpd were in operation in 1974.

Soviet exports of crude oil and petroleum products averaged nearly 2.4 million bpd. Crude oil constituted about 70% of all petroleum exports. The 48-inch-diameter Kuybyshev-Tikhoretsk-Novorossiysk crude oil pipeline was near completion by yearend. The pipeline will connect producing fields with the oil-loading ports of the Black Sea to facilitate exports.

United Kingdom.—Government legislation involving a petroleum revenue tax and 51% Government participation in petroleum operations in the British sector of the North Sea was debated throughout the year. Nationalization remained a possibility if a 51% Government participation was not made available by operating companies.

Three fields in the British sector of the North Sea were scheduled for production in 1975. Combined production from the Hamilton group's Argyll field, from the British Petroleum Forties field, and from the Royal Dutch/Shell and Esso Auk field was expected to total 150,000 bpd in 1975. British Government estimates place production from the North Sea from 2 to 2.8 million bpd by 1980.

Venezuela.—All phases of the petroleum industry were affected by the uncertainties fostered by impending nationalization. Foreign company investment expenditures for 1974 were projected at well over $300 million, but were revised downward as the method and pattern of nationalization came under prolonged debate. However, exploration activities did bring promising results with the discovery of two new fields. The state oil company, Corporación Venezolano de Petróleo (CVP), reported a wildcat discovery in western Monogas flowing at 4,500 bpd, and Mobil Oil Corp. reported a discovery in Lake Maracaibo flowing at 5,400 bpd. Drilling activity, combined with higher oil prices, added nearly 1 billion barrels to Venezuela's proven crude oil reserve, raising the total to 15 billion barrels by yearend.

Venezuela's crude oil production declined significantly as a result of cutback measures in effect in April 1974. Government regulations required that gas flaring be limited to 2% of production, thus reducing the daily production average from nearly 3.4 million barrels reported in 1973 to less than 3.0 million barrels in 1974. Gas-flaring limitations most seriously affected offshore production, where daily averages were reduced to 2.1 million barrels compared with 2.5 million barrels in 1973.

TECHNOLOGY

During 1974, new technology was developed for offshore applications. Recent developments included the following:[10] (1) Testing of electrohydraulic and acoustical subsea control systems as alternatives to all-hydraulic and total-electric systems; (2) introduction of several advanced tools for more efficient installation of pilings; (3) marketing of a multistage centrifugal compressor which reduced platform space requirements; (4) introduction of additional refinements in seismic equipment; and (5) development of a new navigation system capable of operating continuously up to 250 miles offshore.

In addition, sea tests in the Gulf of Mexico under actual producing conditions led Subsea Equipment Associates Ltd. and Lockheed Petroleum Services, Ltd., to claim operational capability for their shallow-water, atmospheric well-completion methods.[11] Work on the two systems at yearend was directed toward developing capabilities to manifold wells and lay underwater flowlines between facilities.

Sea tests for an offshore drilling structure that may eliminate many problems currently experienced with conventional offshore platforms were also scheduled.[12] Designated as the "Tension Leg Platform" by its designer (Deep Oil Technology, Inc.), the structure is a buoyant platform held in place by vertical cables attached to anchors. The cables remain taut at all times to prevent heaving as well as lateral movement.

Another type of drilling rig was designed by Gulf Offshore Co. of Houston to drill infill and replacement wells on producing platforms without interfering with normal production operations.[13] The new rig design saves two-thirds of the platform space normally required. Construction of the rig is facilitated by utilizing 30,000-pound modular units, which are assembled with a special crane.

Bethlehem Steel Corp. also introduced a new offshore rig designed to extend the water-depth capacity of jack-up platforms.[14] The advanced design features telescoping legs which extend jack-up capability to water depths of 377 feet. Most jack-ups are rated at depths of less than 300 feet. The first rig with the new design is scheduled for delivery in late 1976.

Two new products to protect marine areas from oil spills were introduced. The first device is a semisubmersible barrier developed by the Bridgestone Tire Co. of Japan.[15] In effect, the barrier acts as a fence that extends approximately 1.5 feet above water and about 2 feet below the surface. The second product is a barrier marketed by Steltner Development and Manufacturing Co., Ltd., St. Catharines, Ontario, Canada.[16] The developers claim that this device also can be used to channel spills during cleanup operations.

In March 1974, El Paso Natural Gas Co. announced a series of experiments to evaluate the concept of massive hydraulic fracturing as a viable alternative to nuclear stimulation of vast, low-permeability Rocky Mountain natural gas reservoirs.[17] The experimental program involves 18 separate stages of hydraulic fracturing over a 4-year period at two wells in Wyoming. The initial stage of the program commenced in September when 277,000 gallons of fluid with 775,000 pounds of sand were pumped into the first test well. Evaluation of this effort was incomplete at yearend, but it was apparent that initial gas-production rates after fracturing were only one-third of the values predicted.

In related experiments,[18] the Federal Government and 15 industrial sponsors began a joint program to compare costs of massive hydraulic fracturing with cost data obtained from the 1973 Rio Blanco nuclear stimulation project in Colorado. An additional nuclear stimulation experiment was proposed for a test site in Wyoming, but funding for the project was uncertain at yearend.

A new screw percussion bit designed to

[18] Work cited in footnote 16.

perform the same functions as rock, drag, and percussion bits was marketed during 1974.[19] Screw action removes cuttings in soft formations, but the hammer actuates for percussion drilling in hard formations. The bit was field-tested in Alaska.

A drilling mud additive to eliminate the dangerous effects of hydrogen sulfide on personnel and equipment was tested in the field and laboratory during the year.[20] The material reacts on contact with hydrogen sulfide to form safe, stable pyrite. Reaction efficiency is directly proportional to bottom-hole pressure. Moreover, the reaction is irreversible and is not influenced by pH, temperature, or time.

Continental Oil Co. developed a simplified device for shutting in pressure observation wells at the bottom of the drill hole to prevent fluid accumulation in the wellbore.[21] The device gives a positive shut-in of the wells during interference and pulse tests, thereby permitting straightforward analysis. A U.S. patent is pending.

A new electromechanical derrick-floor test system was developed for inspecting drill pipe during removal from the well.[22] Defects such as transverse fatigue cracks, corrosion, and mechanical cuts are detected as pipe is pulled at speeds up to 90 feet per minute. The testing apparatus is mobile and can also be utilized to inspect tubing strings.

Simultaneous rotation and reciprocation is possible with a new cementing tool introduced in 1974 by Fishing Tools, Inc.[23] The tool contains a cementing head and a hydraulically powered swivel that enables the operator to raise or lower pipe while it is being rotated. Initially, the tool will be marketed on the gulf coast.

A new annulus fluid was developed to facilitate the removal of drillpipe.[24] The fluid also lubricates and protects the pipe until it is pulled. In addition, logging and fishing tools were able to move easily through the drill hole when the fluid was employed.

In 1974, the Bureau of Mines research program was directed to enhance recovery of oil and gas based on a cooperative effort with industry. The program objective was to accelerate petroleum production and increase proved reserves. Field work was performed under contracts with industrial companies. Backup laboratory research was to be performed partly by the Bureau and partly by universities through grants. Field demonstrations of enhanced recovery methods were initiated on chemical explosive fracturing, massive hydraulic fracturing, and micellar-polymer flooding and will require 3 to 4 years to complete. All these projects were in early stages of development and expenditures, but will be expanded for the next several years.

Still gas for fuel	163,905	156,967	170,998	176,758	175,724
Miscellaneous products	14,843	14,915	15,284	18,934	24,263
Plant condensate	--	--	--	1,869	6,106
Total domestic demand	5,364,478	5,552,560	5,990,316	6,317,303	6,069,471
Stocks of all oils:					
Crude oil and lease condensate	276,367	259,648	246,395	242,478	265,020
Unfinished oils	98,989	100,574	94,761	99,154	106,031
Natural gasoline [6]	6,088	5,163	4,802	6,160	6,480
Plant condensate	958	1,013	1,273	1,675	1,070
Refined products	635,459	677,549	611,748	658,840	695,045
Total	1,017,861	1,043,947	958,979	1,008,307	1,073,646

---

p Preliminary (except for domestic production of crude oil and lease condensate).

[1] U.S. Department of the Interior data for crude oil, unfinished oils, and plant condensate; U.S. Department of Commerce and Federal Energy Administration data for all other imports. Imports of crude oil include some Athabasca hydrocarbons.

[2] Represents the difference between supply and indicated demand for crude petroleum.

[3] Minus sign represents withdrawal from stocks, which is added to total disposition; plus sign represents stocks increase, which is subtracted from total disposition.

[4] U.S. Department of Commerce data.

[5] Produced at petroleum refineries. Demands for ethane and liquefied gases used for petrochemical feedstocks are excluded. Demand data for these products for petrochemical feedstocks used are included under the items "Ethane" and "Liquefied gases."

[6] Includes isopentane.

Table 3.—Supply and demand of all oils in the United States, by month

(Thousand barrels)

---

[p] Preliminary (except for domestic production of crude oil and lease condensate).

[1] U.S. Department of the Interior data for crude oil, unfinished oils, and plant condensate; U.S. Department of Commerce and Federal Energy Administration data for all other imports. Imports of crude oil include some Athabasca hydrocarbons.

[2] Represents the difference between supply and indicated demand for crude oil.

[3] Minus sign represents withdrawal from stock, which is added to total disposition; plus sign represents stocks increase, which is subtracted from total disposition.

[4] U.S. Department of Commerce data.

[5] Liquefied refinery gas.

[6] Liquefied petroleum gas.

[7] Produced at petroleum refineries. Demands for ethane and liquefied gases used for petrochemical feedstocks are excluded. Demand data for these products for petrochemical feedstock use are included under items "Ethane" and "Liquefied gases."

[8] Includes January data of 372,000 barrels.

[9] Includes isopentane.

Table 4.—Supply, demand, and stocks of all oils in 1974, by PAD district
(Thousand barrels)

	District I	District II	District III	District IV	Total District I–IV	District V	Total United States
Domestic production:

Table 12.—Production, reserves, and undiscovered recoverable resources of crude oil for the United States, December 31, 1974 [1]

(Billion barrels)

Area	Cumulative production	Reserves			Range of undiscovered recoverable resources [2]
		Demonstrated		Inferred [3]	
		Measured [4]	Indicated [5]		
Lower 48 States, onshore	99.892	21.086	4.315	14.3	29–64
Alaska, onshore	.154	9.944	.013	6.1	6–19
Total onshore	100.046	31.030	4.328	20.4	37–81
Lower 48 States, offshore	5.634	3.070	.308	2.6	5–18
Alaska, offshore	.456	.150	([6])	.1	3–31
Total offshore	6.090	3.220	.308	2.7	10–49
Grand total	106.136	34.250	4.636	23.1	50–127

[1] Onshore and offshore to a water depth of 200 meters (656 feet). Cumulative production and estimates of reserves and resources reflect an assumed recovery of about 32% of the oil. Some portion of the remaining oil-in-place is recoverable through application of improved recovery techniques. Estimates are based on figures released by API in April 1975.

[2] The low value of the range is the quantity associated with a 95% probability (19-in-20 chance) that there is at least this amount. The high value is the quantity with a 5% probability (1-in-20 chance) that there is at least this amount. Totals for the low and high values are not obtained by arithmetic summation; they are derived by statistical methods.

[3] Resources estimated to be recoverable in the future as a result of extensions, revisions of estimates, and new pays in known fields beyond those shown in indicated reserves.

[4] Identified resources that can be economically extracted with existing technology. Estimates are the "proved reserves" of API.

[5] Identified resources, economically recoverable if known fluid-injection technology is applied. Estimates are from APL.

[6] Negligible.

Source: Derived from table 1, U.S. Geol. Survey Circ. 725.

[1] From reports of Committee of Petroleum Reserves, American Petroleum Institute. Included are estimated quantities of crude oil that geological and engineering data demonstrate with reasonable certainty to be recoverable from known reservoirs under existing economic and operating conditions.

[2] Included with "Other States."

[3] Includes offshore reserves.

[4] These data include the estimate of proved reserves in the Prudhoe Bay Permo-Triassic reservoir, discovered in 1968. The estimate is based on the analysis of extensive engineering and geologic data; however, revisions may be required when actual production performance becomes available.

[5] Includes Arizona, Missouri, Nevada, South Dakota, Tennessee, and Virginia.

p Preliminary except for crude petroleum production.

[1] Reported to the Bureau of Mines. Imports of crude oil include some Athabasca hydrocarbons.

[2] Represents the difference between supply and indicated demand for crude petroleum.

[3] U.S. Department of Commerce.

p Preliminary.

[1] Includes some Athabasca hydrocarbons.

[2] "Other hydrocarbons and hydrogen" is defined as including all hydrogen, process natural gas, tar sand bitumen, gilsonite, shale oils, and other naturally occurring hydrocarbon mixtures consumed as raw materials in the production of finished products.

[3] Production at gas-processing plants shown as direct transfers and omitted from the input and output at refineries.

Domestic demand:				
LPG for fuel and chemical use	249,767	292,887	281,624	269,462
LRG for fuel use	87,089	84,019	89,654	83,207
LRG for chemical use	32,152	36,743	38,040	35,575
Total domestic demand	369,008	413,649	409,318	388,244
Propane (including propylene):				
Production:				
At gas-processing plants	212,143	218,039	212,886	206,539
At refineries:				
For fuel use	71,934	69,038	73,531	62,298
For chemical use	21,512	25,024	25,329	25,155
Total production at refineries	93,446	94,062	98,860	87,453
Total production	305,589	312,101	311,746	293,992
Stocks, end of year:				
Plant propane stocks:				
At plants	56,779	48,219	59,704	64,713
At refineries	769	190	357	97
Total plant propane stocks	57,548	48,409	60,061	64,810
Refinery propane and/or propylene stocks:				
For fuel use	5,050	4,959	4,399	3,684
For chemical use	263	193	187	112
Total refinery propane and/or propylene stocks	5,313	5,152	4,586	3,796
Total stocks	62,861	53,561	64,647	68,606
Imports	11,606	15,851	25,791	21,464
Exports	4,685	6,502	5,500	4,971
Plant propane used at refineries	3,273	3,934	2,755	3,465
Domestic demand:				
Plant propane	197,138	232,593	213,770	214,818
Refinery propane and/or propylene:				
For fuel use	71,185	69,129	74,091	63,013
For chemical use	21,392	25,094	25,335	25,230
Total refinery propane and/or propylene domestic demand	92,580	94,223	99,426	88,243
Total domestic demand	289,718	326,816	313,196	303,061
Butane (including butylene):				
Production:				
At gas-processing plants	88,544	88,924	88,766	87,171
At refineries:				
For fuel use	13,765	12,940	13,036	13,598
For chemical use	5,886	5,673	6,666	6,442
Total production at refineries	19,651	18,613	19,702	20,040
Total production	108,195	107,587	108,468	107,211
Stocks, end of year:				
Plant butane stocks:				
At plants	13,571	10,389	15,289	20,992
At refineries	1,614	1,425	1,369	2,212
Total plant butane stocks	15,185	11,814	16,658	23,204

See footnotes at end of table.

---

p Preliminary.

[1] Includes underground stocks at plants and refineries, in thousand barrels. At plants: Ethane, 1973, 3,921; 1974, 3,183; propane 1973, 52,090; 1974, 57,186; butane, 1973, 12,248; 1974, 18,522; butane-propane mixtures, 1973, 192; 1974, 894; and isobutane, 1973, 6,341; 1974, 9,809. At refineries (includes LRG): Propane, 1973, 4,074; 1974, 3,730; butane, 1973, 2,725; 1974, 3,324; butane-propane mixtures, 1973, 444; 1974, --; and isobutane, 1973, 765; 1974, 507.

[2] Includes No. 4 fuel oil, in thousand barrels: 1972, 3,723; 1973, 3,449; 1974, 4,116. Data for 1971 not available.

[3] Includes foreign crude oil to be burned as fuel, in thousand barrels: 1972, 10,419; 1973, 19,105; 1974, 7,508. Data for 1971 not available.

[4] Produced at petroleum refineries. Data for LRG petrochemical feedstocks are included with those for "Liquefied gases."

NOTE.—"Stocks at refineries" include stocks at refineries and bulk terminals operated by refining and refined products pipeline companies, including pipeline fill. "Stocks at plants" include stocks at plants and terminals operated by natural gas processing companies and natural gas liquids stocks at terminals of pipeline companies, including pipeline fill.

[p] Preliminary.

[1] American Petroleum Institute data for 1972 and 1973. U.S. Department of Transportation, Federal Highway Administration data for 1974.

[2] Alaska, Hawaii, and Nevada (1974) included with California.

[3] Delaware and Georgia (1974) included with Pennsylvania.

[4] Nebraska and Missouri included with Kansas.

[5] Tennessee included with Kentucky.

[6] North Carolina and West Virginia included with Virginia.

[7] Wisconsin included with North Dakota.

Total	927.2	971.3	1,074.9	1,185.0	1,081.1

[1] Includes diesel fuel.

[2] Includes range oil.

[3] Includes approximately 23 milllion barrels of distillate No. 2, approximately 2.1 million barrels of distillate No. 4 fuel oil used at steam-electric plants, and 6.3 million barrels of kerosine-type jet fuel used by electric utility companies.

[4] Includes 23.6 million barrels of distillate No. 2 and 3.0 million barrels of distillate No. 4 fuel oil used at steam-electric plants. Also included are 5.2 million barrels of kerosine-type jet fuel used by electric utility companies.

p Preliminary.

[1] Figures represent crude oil used as fuel on pipelines, which is considered part of the demand for distillate.

[2] Includes No. 4 fuel oil, in thousand barrels: PAD district I, 1973—3,068, 1974—3,622; PAD district II, 1973—129, 1974—33; PAD district III, 1973—170, 1974—438; PAD district IV, 1973—15, 1974—16; PAD district V, 1973—67, 1974—7.

p Preliminary.

[1] Represents crude oil used as fuel on leases and for general industrial purposes.

[2] Sulfur content, in thousand barrels: 0%-0.50%, 1973—96,690, 1974—97,671; 0.51%-1.00%, 1973—82,500, 1974—103,358; 1.01%-2.00%, 1973—102,842, 1974—105,028; over 2.00%, 1973—72,565, 1974—84,434.

[3] Sulfur content, in thousand barrels: 0%-0.50%, 1973—245,740, 1974—196,234; 0.51%-1.00%, 1973—137,778; 1974—106,681; 1.01%-2.00%, 1973—73,745, 1974—75,745; over 2.00%, 1973—164,106, 1974—155,675.

[4] Includes foreign crude oil to be burned as fuel, in thousand barrels: PAD district I; 13,153; PAD district II, 1,916; PAD district V, 4,036.

[5] Includes foreign crude oil to be burned as fuel, in thousand barrels: PAD district I, 4,787; PAD district II, 2,721.

Table 56.—Posted price per barrel of petroleum at wells in the United States in 1974, by grade[1]

Grade	Price per barrel
Pennsylvania grade:	
Bradford and Allegheny districts	$6.88
Southwest Pennsylvania	6.12
Corning grade	5.17
Western Kentucky	5.20
Indiana-Illinois	5.20
Coldwater, Michigan	5.00
Oklahoma-Kansas:	
34°-34.9° API	5.11
36°-36.9° API	5.15
Texas, Panhandle (Carson, Gray, Hutchinson, Wheeler Counties), 35°-35.9° API	5.10
West Texas, 30°-30.9° API (sweet)	5.11
Lea County, New Mexico, 30°-30.9° API (sour)	5.00
South Texas, Mirando, 24°-24.9° API	5.30
East Texas	5.20
Conroe, Texas	5.30
Texas:	
30°-30.9° API	5.05
20°-20.9° API	4.95
Louisiana, 30°-30.9° API	5.15
Caddo-Pine Island, Louisiana, 36°-36.9° API	5.04
Magnolia Smackover Limestone, Arkansas, 31°-31.9° API	4.84
Elk Basin, Wyoming (including Montana), 30°-30.9° API	4.86
California:	
Coalinga, 32°-32.9° API	5.01
Kettlemen Hills, 37°-37.9° API	5.26
Midway Sunset, 19°-19.9° API	4.28
Wilmington, 24°-24.9° API	4.68

---

[p] Preliminary.

[1] Imports for onshore use of military jet fuel, distillate and residual fuel oils, and receipts from Puerto Rico, the Virgin Islands, and Guam included in these data are based on figures reported to the U.S. Department of the Interior. All other import figures are compiled from U.S. Department of Commerce data.

Table 62.—Crude oil and petroleum products[1] imported into the United States, by country and receiving PAD district

p Preliminary.

[1] Imports of crude oil, unfinished oils, and plant condensate are reported to the Bureau of Mines. All other import data are compiled from U.S. Department of Commerce and Federal Energy Administration data.

[2] Includes quantities imported duty-free for supply of vessels and aircraft engaged in foreign trade.

Phosphate Rock

By W. F. Stowasser[1]

Estimated world production in 1974 was approximately 122 million short tons, an increase of about 12% over the 1973 production level. This was the highest annual production recorded and probably the highest annual growth rate. For the fourth consecutive year, world demand exceeded production, further reducing world stocks.

In the United States, the average unit value of phosphate rock increased from $5.66 per ton f.o.b. plant in 1973 to $10.98 per ton f.o.b. plant. World export prices for phosphate rock and fertilizer increased several times during the year and attained levels that were not predictable a year ago. The high prices of phosphate rock and continuing strong demand from world markets promoted plans to increase production from existing mines and from new mining areas. The demand for food from an exploding world population is believed to be the principal cause for the unprecedented demand for phosphatic fertilizers. Although the world population was only 1 billion in 1830, it increased to 2 billion by 1930, to 3 billion by 1960, and to over 4 billion by 1974. This accelerating population rate was the result of a declining death rate without a compensating corresponding decrease in the birth rate. The problems of feeding today's population, particularly in developing countries, are well documented. These problems are expected to intensify as the population increases to about 6 billion to 8 billion by the year 2000.

Although it is possible to double and triple yields per acre of corn, wheat, and rice with the application of chemical fertilizers, it is also necessary to furnish more water from extensive irrigation systems, power for pumps, and herbicides to control weeds. An infrastructure is required to store and distribute larger crops. Much progress in these areas was made in the 1960's but in 1972 a series of events started that reduced the world's ability to feed its population. Unfavorable weather in 1972 reduced crop yields in the U.S.S.R., the People's Republic of China, the Indian subcontinent, and a zone in Africa south of the Sahara. In 1973, harvests in the world improved but not enough to meet the demand for food. In 1974 the world prices of petroleum products and phosphatic fertilizers increased 3 to 4 times compared with the prices existing 1 to 2 years ago. The increase in the price of energy and fertilizer feedstocks put the "green revolution" out of financial reach of many developing countries and contributed to the increased cost of producing food in the developed countries.

[2] Measured by sold or used plus imports minus exports.

Legislation and Government Programs.—With companies planning to open new mines on public and private lands in Florida, North Carolina, and several Western States, permission to mine from regulatory bodies controlling county, State, and Federal lands was not frequently granted during 1974. An application to mine phosphate reserves in the Los Padres National Forest of California, made in 1969, has not been approved. Four companies had applied for preference right leases to mine phosphate rock in the Osceola National Forest, in northern Florida, during the 1969 to 1972 period. An Environmental Impact Statement for the Osceola National Forest was completed and published in 1974, however, a decision by the U.S. Department of the Interior to deny or grant the leases was still pending at yearend. A number of applications to mine phosphate rock in the Caribou National Forest of Idaho were made in 1974. These requests were tabled until a regional Environmental Impact Statement could be prepared in compliance with the National Environmental Protection Act.

New mines in North Carolina are regulated by the State Mining Act of 1971 (G.S. 74–46 through 74–68). Permits to mine are issued only after the appplicant furnishes sufficient information to assure that (1) the usefulness, productivity, and scenic values of all lands and waters involved in mining within the State will receive the greatest practical degree of protection and restoration and (2) no mining will be done in the State unless plans for such mining include reasonable provisions for protection of the surrounding environment and for reclamation of the area of land affected by mining. In addition, regulations to provide for management of water withdrawal and use in designated "Capacity Use Areas" must be followed by application for Water Use Permits from the Board of Water and Air Resources.

The State of Florida, Department of Pollution Control, promulgated the rules on air pollution and the Florida Pollution Control Board published the rules on pollution of waters. In addition to State regulations and those of the Southwest Florida Water Management District, the counties to the south and southwest of Polk County, specifically Hillsborough, Manatee, Hardee, and Desoto Counties, adopted ordinances to regulate mining and earthmoving. In Hillsborough County, Ordinance No. 74–6, the "Hillsborough County Phosphate Mining Ordinance," requires submission of an Application for Development Approval of a Development of Regional Impact pursuant to Chapter 380, Florida Statutes, a mining and reclamation plan, evidence of financial responsibility, and copies of applications to and approvals from all applicable Federal, State, and local agencies.

The rules and regulations of the Hillsborough County phosphate mining ordinance are highlighted in the Construction and Operation and Reclamation Sections. Neither mining nor settling ponds will be permitted within 500 feet of a public park boundary, residences, or land zoned for residences; within 200 feet of public right-of-way or private easement for drainage, utility, or road purposes; and must be 200 feet from permittee's property line. Control of excavated material placement and height, noise levels, soil vibration levels, blasting, and ground water withdrawal is planned. Diversion of natural streams or lakes will be restricted. Construction on the 25-year flood elevation of surface water courses and mining or placement of fill on the 25- to 100-year flood elevation will be permitted only if the permittee can show that countermeasures will insure a reduction of the net effect of water surface elevation of all floods. All dams for settling or thickening ponds will be located, designed, constructed, and maintained in compliance with the rules and regulations of the State Department of Pollution Control. Slimes will be impounded in settling ponds and will be fenced and posted. Air quality and rainfall will be monitored on the permittee's property.

Mined-out lands not covered by settling ponds and settling ponds on mined-out lands or on natural ground are to be reclaimed under separate regulations. Mined-out land will be reclaimed to sufficiently level surfaces to support farm and agricultural activities; the ratio of slopes will not exceed one vertical to six horizontal; and lands will be revegetated. Permanent water bodies created will conform to specified slopes, depths, and drainage. Reclamation will be completed within 1 year after ending mining in a unit. Areas placed into settling ponds will be considered reclaimed when all provisions described for mined-out land are met. A time limit is not specified but permittees are expected to show the schedule in the Mining and Reclamation Plan.

The ordinances of the other counties are similar and, in some instances, more specific than Hillsborough County's ordinance. These are available from the respective Boards of County Commissioners.

On October 22, 1974 the Environmental Protection Agency (EPA) published in the Federal Register[2] a notice of proposed rulemaking pursuant to section III of the Clean Air Act, as amended (39 F.R. 37602 Oct. 22, 1974). The proposed regulation establishes standards of performance for new phosphate fertilizer industry plants, including wet process phosphoric acid, superphosphoric acid, diammonium phosphate, and triple superphosphate plants and storage facilities.

The EPA published in the Federal Register[3] the final effluent limitations guidelines for existing sources and standards of performance and pretreatment standards for new sources in the phosphate manufacturing category of point sources, by amending 40 CFR, Chapter I, Subchapter N, and adding a new subpart 422. The provisions of this subpart are applicable to discharges of pollutants from the manufacture of phosphoric acid, phosphorus pentoxide, phosphorus pentasulfide, phosphorus trichloride, and phosphorus oxychloride directly from elemental phosphorus.

DOMESTIC PRODUCTION

Domestic production of marketable phosphate rock was 45,686,000 tons, an increase of 3,549,000 tons, or 8.4%, over that of 1973. The value of the marketable rock was $501,429,000, an increase of 110% over that of 1973. The average grade of phosphate ore mined in the United States was 13.3% P_2O_5, and the average grade of marketable rock was 30.8% P_2O_5. The average weight recovery of concentrate and rock marketable as mined was 29.3%, and the P_2O_5 recovery averaged 67.7%. Of the total marketable production in the United States, Florida and North Carolina produced 36,980,000 tons (80.9%), the Western States produced 6,295,000 tons (13.8%), and Tennessee produced 2,411,000 tons (5.3%).

Florida and North Carolina.—Production of marketable phosphate rock was 36,980,000 tons, an increase of 2,553,000 tons, or 7.4%, over that of 1973. The value of marketable rock was $408,979,000, an increase of $217,325,000, or 113.4%, over that of 1973.

The average grade of phosphate ore mined was 12.5% P_2O_5, and the average grade of marketable rock was 31.4% P_2O_5. The average weight recovery of concentrate and rock marketable as mined was 26%, and the average P_2O_5 recovery was 65.6%. A majority of producers in Florida and North Carolina were able to increase production in 1974; however, the largest increases were posted by International Minerals & Chemical Corp. (IMC) and Texasgulf Inc. International Minerals & Chemical Corp.'s new Phosphoria mine started operating in May. The plant is designed to recover pebble and the concentrate feed is pumped to the Noralyn concentration plant. Texasgulf announced plans for expansion of rock and fertilizer capacity at the Lee Creek mine in North Carolina. Implementation of these plans proceeded in 1974 with erection of a 30-inch hydraulic dredge to remove overburden and a 50-yard dragline.

[2] Federal Register, v. 39, No. 205, Oct. 22, 1974, pp. 37, 602-37, 607.

[3] Federal Register, v. 39, No. 35, Feb. 20, 1974, pp. 6580-6588.

Agrico Chemical Co., Borden, Inc., Brewster Phosphates, Gardinier, Inc., W. R. Grace & Co., International Minerals & Chemical Corp., Mobil Oil Corp., Poseidon Mines, Inc., Occidental Petroleum Corp., USS Agri-Chemicals, Inc., and Swift Chemical Co. produced marketable rock from Florida land-pebble phosphate fields. Howard Phosphate Co., Kellogg Co., Loncala Phosphate Co., and Manko Co. mined 41,000 tons of soft rock in Florida.

Agrico Chemical Co., a subsidiary of the Williams Companies and Kennecott Copper Corp. announced plans to build a new phosphate mining and manufacturing facility near Washington in Beaufort County, N.C. The mine will be designed to produce 4 to 5 million tons of marketable phosphate rock per year from an estimated 300-million-ton reserve. A 400,000- to 600,000-ton-per-year phosphoric acid plant will be constructed and a million tons of diammonium phosphate and ammonium polyphosphate will be produced at the mine site. A schedule of construction for the mine and plant was not announced. Construction proceeded on Agrico Chemical Co.'s wet phosphate rock handling and loading terminal at the former site of the Big Bend Industrial Park on Hillsborough Bay, Fla. The construction of the Fort Green mine in Polk County, Fla., designed to produce a total of 2 to 2.5 million tons per year of pebble and concentrate, was expected to start by the end of the year. The flotation plant was scheduled to be completed in 1975.

Beker Industries Corp. exercised its options to acquire properties in Manatee County, Fla., with reserves estimated to be 60 million tons. The purchase was completed before the company's attempt to have the Florida Land and Water Adjudicatory Commission override the Manatee County Commission's denial of a development order. The application for a development order was in the appeal process at the end of the year.

The Hillsborough County Commission granted its first mining permit in August to Brewster Phosphates. The site of the proposed phosphate mine is near Fort Lonesome in southeastern Hillsborough County. Of the 18,367 acres in the tract, only 9,793 acres will be mined to extract an estimated 50 million tons of marketable phosphate rock. The mining rate planned is 3 million tons per year with operations scheduled to start in 1976.

Occidental Petroleum Corp. concluded a barter agreement with the U.S.S.R. The details were not published; however, it was understood that the U.S.S.R. will produce and option to purchasers in the United States at world market prices 3.4 million short tons of anhydrous ammonia per year, 1.1 million short tons of potash per year, and from 1.1 to 1.7 million short tons of urea per year. If these commodities are not purchased in the United States, the U.S.S.R. has the option of marketing internationally. The Occidental Petroleum Corp. will furnish 1.1 million short tons of superphosphoric acid per year to the U.S.S.R. The barter is planned to start in 1978 and to terminate in 1998. Occidental Petroleum Corp. will consume about 2.7 million tons per year to satisfy this commitment, or 54 million tons of phosphate rock over the life of the contract.

The Swift Chemical Co. advised the Manatee County Commissioners that it was reviewing plans to obtain approval to mine phosphates from 11,000 acres in the northern part of Manatee County. The application for the mining permit will be made in the near future.[4]

A report discussing the economic significance to Florida and the Nation of the phosphate industry was published.[5]

---

[4] Bradenton Herald, July 18, 1974.

[5] Wang, Kung-Lee, B. W. Klein, and A. F. Powell. Economic Significance of the Florida Phosphate Industry. BuMines Inf. Circ. 8653, 1974, 51 pp.

Western States.—Production of marketable phosphate rock was 6,295,000 tons, an increase of 1,097,000 tons over that of 1973, or 21.1%. Agricultural Products Corp. (Beker Industries Corp.), J. R. Simplot Co., and Stauffer Chemical Co. were the companies principally responsible for the increase in production. The value of the marketable rock increased to $73,985,000, or 116% above that of 1973. The average grade of mined phosphate rock was 23.2% P_2O_5. The average grade of rock used direct was 26.4% P_2O_5, and the average grade of beneficiated rock was 32.1% P_2O_5. The average grade of total marketable rock was 28.4% P_2O_5. Of the total rock produced in the Western States, 65.3% was used direct and 34.7% was beneficiated. The weight recovery of the combined beneficiated concentrates and rock used as mined was 65.7%, and the average P_2O_5 recovery was 80.5%.

Agricultural Products Corp., Monsanto Company, J. R. Simplot Co., and Stauffer Chemical Co. mined and processed phosphate rock in Idaho. In Montana, Cominco American, Incorporated, and Rocky Mountain Phosphate Co. recovered phosphate rock from underground mines near Garrison. Stauffer Chemical Co. mined phosphate rock in Wyoming and in two areas in Utah. The Meramec Mining Co., Sullivan, Mo., continued to recover apatite concentrates from its Pea Ridge iron ore mine tailings.

Although none of the producing companies in the Western States announced any new expansion plans in 1974, Earth Sciences, Inc., in a joint venture with National Steel Corp. and Southwire Co., acquired a block of phosphate reserves consisting of seven properties from John and Elizabeth Archer. Plans are to construct a triple superphosphate plant near Cedar City, Utah, and to react the sulfuric acid derived from processing alunite with phosphate rock from the Archer properties. The details of mining, beneficiation, and fertilizer production were not completed.

Valley Nitrogen Products, Inc., secured mining rights from Duval Corp. and Tenneco Corp. on 1,300 acres of land in Wyoming as a possible source of phosphate rock.[6]

International Minerals & Chemical Corp. requested that the Bureau of Land Management approve the mining plan for their existing lease, Husky #1 property, in Idaho. The U.S. Department of the Interior and the U.S. Department of Agriculture determined that the expansion of phosphate mining activity on Federal leases in southeastern Idaho constituted a major Federal action as defined by the National Environmental Policy Act of 1969 and, therefore, requires the preparation of an environmental impact statement. The preparation of an environmental impact statement by the U.S. Departments of the Interior and Agriculture was initiated and is expected to be completed and filed with the Council on Environmental Quality in mid-1976.

Tennessee.—Production of marketable phosphate rock was 2,411,000 tons, a decrease of 101,000 tons, or 4% less than reported in 1973. The value of the marketable rock increased from $12,799,000 in 1973 to $18,465,000 in 1974, an increase of 44.3%.

The average grade of mined ore was 19.9% P_2O_5, the average weight recovery of concentrates was 63.2%, and recovery of P_2O_5 averaged 78.9%. A small quantity of rock was mined by several companies and was used in the electric furnaces without the benefit of beneficiation.

Hooker Chemical & Plastic Corp., Monsanto Industrial Chemical Co., Stauffer Chemical Co., M. C. West, Inc., and the Tennessee Valley Authority mined phosphate rock in Tennessee and reduced the rock in electric furnaces to elemental phosphorus.

M. C. West, Inc., started mining and beneficiating phosphate rock for the merchant market in the second half of 1974.

W Withheld to avoid disclosing individual company confidential data.

[1] Includes North Carolina.

[2] Includes Idaho, Missouri, Montana, Utah, and Wyoming.

[3] Data may not add to totals shown because of independent rounding.

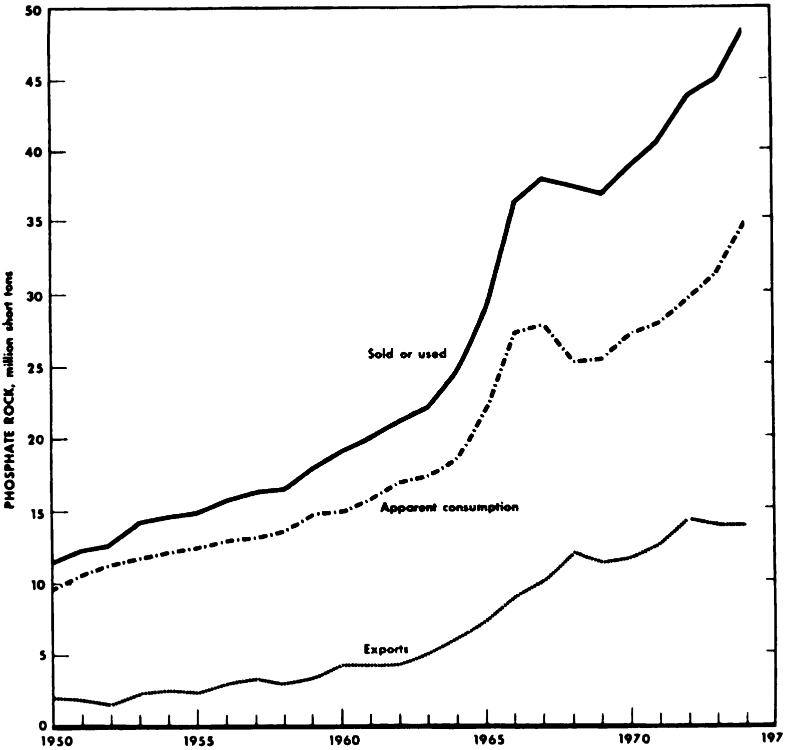

Figure 1.—Phosphate rock (sold or used), apparent consumption, and exports.

CONSUMPTION AND USES

Apparent consumption of marketable phosphate rock increased 11.2% above that reported in 1973. According to producers' reports, the quantity of marketable rock sold or used was 48,435,000 tons. This was an increase of 7.5% over the quantity sold or used in 1973. The domestic market consumed 71.3% of this total and 28.7% was exported.

The consumption pattern in the United States was 28,263,000 tons (81.8%) for fertilizer and 5,925,000 tons (17.2%) for elemental phosphorus production. To produce defluorinated rock and other minor purposes 350,000 tons (1.0%) was used.

The percent distribution by grade of marketable rock consumed in the United States is compared with the percent distribution in 1973 in the following tabulation:

Grade	Percent distribution	
percent BPL[1]	1973	1974
Less than 60	8.7	5.6
60–66	11.9	20.8
66–70	40.9	42.0
70–72	12.3	12.2
72–74	16.7	11.6
Over 74	9.5	7.8

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Florida and North Carolina.—The quantity of phosphate rock sold or used increased from 36,916,000 tons in 1973 to 39,920,000 tons in 1974. Of this total sold or used in 1974, 65.9% was consumed in the domestic fertilizer market and the balance, 33.2%, was exported, with a minor quantity used domestically for defluorinated rock, elemental phosphorus and other miscellaneous applications. The consumption pattern of the overall domestic fraction was 26,296,000 tons (98.6%) for fertilizer, 326,000 tons (1.2%) for defluorinated rock, and the balance was converted into elemental phosphorus or used for other minor purposes.

The percent distribution by grade of marketable rock sold or used from Florida and North Carolina in 1974 compared with that of 1973 follows:

Grade	Percent distribution	
percent BPL[1]	1973	1974
Less than 60	0.3	0.2
60–66	9.7	17.0
66–70	45.9	47.2
70–72	14.1	14.3
72–74	18.5	11.9
Over 74	11.5	9.4

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Western States.—The quantity of marketable rock sold or used increased 8.2% compared with the quantity sold or used in 1973. Of the total sold or used in 1974, 89.1% was consumed in the domestic market and the balance, 10.9%, was exported. Of the 5,263,000 tons consumed in the domestic market, 37.4% was used for fertilizer and 62.6% was used principally in electric furnaces. A small tonnage was used to produce defluorinated rock.

The percent distribution by grade of marketable rock sold or used from the Western States in 1974 compared with the percent distribution in 1973, is as follows:

Grade	Percent distribution	
percent BPL[1]	1973	1974
Less than 60	37.7	35.8
60–66	22.8	22.5
66–70	20.4	23.5
70–72	6.0	3.5
72–74	12.6	14.3
Over 74	.5	.4

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Tennessee.—The quantity of marketable rock sold or used declined slightly from 2,665,000 tons in 1973 to 2,607,000 tons in 1974. All of this rock was consumed in electric furnaces to produce elemental phosphorus and industrial chemicals. Most of the elemental phosphorus was burned to produce furnace phosphoric acid, the base for sodium tripolyphosphate and dicalcium phosphate, the principal products. A small amount of elemental phosphorus was used to produce anyhydrous derivatives.

The percent distribution by grade of marketable rock sold or used from Tennessee is compared with the percent distribution in 1973 in the following tabulation:

Grade percent BPL[1]	Percent distribution 1973	Percent distribution 1974
Less than 60	66.4	19.7
60–66	19.8	75.6
66–70	12.9	4.7
70–72	--	--
72–74	.9	--
Over 74	--	--

---

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

STOCKS

In Florida and North Carolina, yearend stocks of marketable phosphate rock declined from 8,446,000 tons in 1973 to 5,750,000 tons in 1974. This was the largest percentage decline in stocks over the past 3 years. The decline of 31.9% in 1974 was substantially greater than the 19.2% and 12% stock reductions in 1973 and 1972, respectively.

Significant stocks are not maintained in Tennessee. Sufficient surge is maintained to assure beneficiated rock for the electric furnaces. If merchant rock is produced in the future, it is probable that some stocks will be developed and reported. Stocks are accumulated in the Western States to carry both electric furnace and wet process phosphoric acid plant operations over the winter months when transportation problems develop with frozen ore. Shipments, for the complete year, of ore from mines to plants by either truck or rail are scheduled during the mild temperature months. Significant carryover of stocks from year to year has not been practiced.

PRICES

Prices for various grades of Florida land-pebble phosphate rock published by the Chemical Marketing Reporter are shown in table 8. These prices may be an indication of the current level of new contract prices for land-pebble phosphate rock in the domestic market, since phosphate rock contracts are not published. The price of Tennessee and Western States phosphate rock consumed in electric furnaces also is not published. Acid grade rock that is not exported is, for the most part, consumed by producing companies. A small amount is sold in the merchant market.

The average 1974 unit value[7] of marketable rock as reported by producers, and estimated when unspecified, was $10.98 per ton f.o.b. plant, a significant increase from the $5.66 per ton reported in 1973. The average unit value of land-pebble rock reported sold or used in the domestic market from Florida and North Carolina increased from $5.57 per ton in 1973 to $10.95 per ton in 1974. In the Western States, the unit value of marketable rock sold or used increased from $6.51 per ton in 1973 to $12.08 per ton in 1974. The unit value of marketable rock sold or used in Tennessee increased from $5.18 per ton in 1973 to $7.90 per ton in 1974.

The average unit value of marketable phosphate rock exported from the United States increased from $5.98 per ton in 1973 to $13.96 per ton in 1974. The unit value of marketable rock exported from Florida and North Carolina increased from $5.77 per ton in 1973 to $13.84 per ton in 1974. The unit value of phosphate rock exported from the Western States increased from $9.93 per ton in 1973 to $16.40 per ton in 1974. Tennessee rock was not exported.

The Phosphate Rock Export Association, Tampa, Fla., increased the price of phosphate rock during 1974 as shown in table 9. The Office Cherifien des Phosphates, Morocco, posted price increases during the year for both Khouribga and Youssoufia rock as shown in table 10. It is noted that the Moroccan export price set by the Office Cherifien des Phosphates is maintained about $20 per ton higher than that posted by the Phosphate Rock Export Association. Prices of phosphate rock produced in Senegal and Jordan follow the price schedule published by Morocco; however, Togo has priced its rock at $68 per short ton f.a.s. (free alongside ship) Kpeme.

FOREIGN TRADE

Of the 13,897,000 tons of marketable phosphate rock reported by producers as exported in 1974, 95.4% originated in Florida and North Carolina and the balance, 4.6%, was exported from the Western States. The quantity of marketable rock exported in 1974 was about the same as the 13,875,000 tons exported in 1973. Exports from Florida, the principal source of marketable rock for the export market, did not change significantly compared with 1973 export tonnage. Exports of marketable rock from the Western States declined 8.7% compared with exports in 1973.

The average calculated unit value of exported phosphate rock increased from $5.98 per ton in 1973 to $13.96 per ton in 1974.

Imports in 1974 were 182,000 tons compared with 65,000 tons imported in 1973. Although the percent increase, 180%, was large, the absolute quantity was a minor part of the United States supply. The value of the imported phosphate rock was $8,999,000 and the average unit value was $49.45 per ton. The Bureau of Census reported 43,531 tons was imported from Mexico, 84,353 tons from the Netherlands Antilles, 31,377 tons from the Spanish Sahara, 22,420 from Israel, and a 20-ton sample from Australia.

WORLD REVIEW

Phosphate rock deposits throughout the world were intensively evaluated for greater production, and exploration for new sources of supply was also intensified. The stimulus was the threefold to fourfold increase in price that was announced near the end of 1973. Significant developments in the world were as follows:

Australia.—The rapid increase in world phosphate rock prices encouraged Queensland Phosphate Pty. Ltd., a subsidiary of Broken Hill South Ltd., to prepare for production, early in 1975, the Duchess phosphate rock deposit rather than proceed to develop the Lady Annie property which could not produce before 1977. Production from Duchess will start at a rate of 20,000 tons per month and is expected to reach 1 million tons per year in 1976. A 25 mile rail line will connect the mine with the port of Townsville. Duchess and a nearby deposit, the Ardmore, contain 1.4 billion tons of phosphate rock of which 40 million tons is 31% P_2O_5, a direct shipping grade. A crushing, screening, and washing plant is under construction.

Brazil.—Serrana de Mineração and the Cimento Itaú group have founded Araxá S.A. Fertilizantes to mine apatite at Araxá, Minas Gerais. The investment was approved by the Industrial Development Council of the Ministry of Industry and Commerce. By 1976, Araxá S.A. is expected to produce at a rate of 628,000 short tons per year.

India.—About 430 tons of phosphate rock per day was mined from the Jhamar Kotra deposits in Rajasthan near Udaipur. The proven reserves are 37 million tons which will permit extraction at a proposed rate of 750,000 tons per year. The production from the Jhamar Kotra mine is used domestically. The meter gage railroad in Rajasthan, incompatible with broad gage lines, and the shortage of rail cars were major obstacles to mine expansion plans.

Israel.—Negev Phosphates Ltd., a subsidiary of the state-owned Israel Chemicals Ltd., plans to increase production at mines in the Negev Desert from a current level of about 750,000 tons per year to 2.8 million tons per year in 1977. Reserves are estimated to exceed 100 million tons.[8]

Jordan.—The Jordan Phosphate Mines Co. plans to triple production of phosphate rock by 1976. If the schedule is accomplished, Jordan will produce 5.4 million tons in 1976, of which more than 50% will be a high-grade (73%–75% BPL) product. Confirmed reserves are of the order of 300 million tons and the resource is 1 billion tons.[9]

Mexico.—Mexico's National Patrimony Ministry announced the discovery of phosphate rock deposits in the Baja California peninsula. Reserves of 3 billion tons were specified.

Morocco.—Under a trade agreement between Morocco and the U.S.S.R., the U.S.S.R. has agreed to supply specialists and equipment to develop a phosphate complex in southern Morocco. The long-term arrangement is designed to have Morocco furnish 5 million tons per year of phosphate rock between 1980 and 1990 and 10 million tons per year after 1990. The length of the agreement was reported to be 30 years. The phosphate mine is in the Meskala region, east of the port of Essaouira. The first estimate made of reserves in this area was 8 billion tons in the top 63 feet of the deposit. The U.S.S.R. will ship to Morocco, between the years 1974 to 1990, sulfur, ammonia, urea, and crude oil. The schedule of shipments for each commodity was not published. Plans to open mines at Benguerir in 1977 to eventually produce 11 million tons per year, and at Sidi Hajjaj in 1980 to develop a production of 11 million tons per year are well advanced. By 1977 the Khouribga mines will be producing at a level of about 22 million tons per year. Production at Youssoufia will remain at 6 to 7 million tons per year. By 1985, Morocco's production, including that planned from the Meskala, could be of the order of 55 million tons per year if all of these plans materialize.

New Zealand.—A large underwater deposit of phosphate nodules between Chatham Island and the Banks Peninsula is being explored as a possible source of phosphates for New Zealand. The phosphorites were reported to be at depths of 1,000 feet or more and the recoverable reserve was estimated to be of the order of 70 million tons.[10]

Pakistan.—The Hazara deposits, that occur in several locations near the city of Abbottabad in the Northwest Frontier Province, are being explored but little is known about the total reserves. At one deposit, the Kabul, considerable development work was completed. The deposit was explored along 2,500 feet of outcrop. The mineralized zone is 10 to 12 feet in thickness, averaging 28% to 32% P_2O_5. The area is badly faulted and folded. The reserve of the Kabul deposit may reach 3 million tons. The rock does not appear to react readily with sulfuric acid.

Peru.—Minero Peru started a brines and phosphate rock pilot plant. The plant was designed to produce 50 tons per day. The commercial plant design is for about 3 million tons per year and is scheduled to start production in 1976 at 800,000 tons per year.

Senegal.—The Senegalese Government announced that it will increase its holding in Compagnie Sénégalaise des Phosphates de Taiba to 50%. The Taiba Company was owned 27.28% by Bureau de Recherches Géologiques et Minières (BRGM), 23.87% by International Minerals & Chemicals Corp. (IMC), 14.3% by Compagnie Financiére Pour l'Outremer (Cofimer) of France, 10.41% by Cie. Central de Cooperation Economique (CCCE), 2.48% by Comiphos, 9.05% by OPCIA, 5.21% by Rhône-Progil, 3.76% by Auxom, 0.46% by OPFIA, and 3.05% by the Senegalese Government.[11]

South Africa, Republic of.—The flotation plant of Phosphate Development Corp. Ltd., treating tailings from the Palabora Mine, is to be expanded. An additional

[11] Industrial Minerals. No. 82, July 1974, pp. 35–36.

900,000 tons per year of concentrates is projected from the expansion.[12]

Spanish Sahara.—The conveyor belt that carries phosphate rock from the mines at Bu Craa to the port of El Aauin was sabotaged by guerillas during the year, interrupting this part of the operation for extended periods. Production was about 2.6 million tons, a substantial increase over production of less than 1 million tons in 1973.

Togo.—In January, Togo raised its holding interest from 35% to 51% in Compagnie Togolaise des Mines du Bénin (Cotomib). In February Cotomib was nationalized. The company was partially owned by W. R. Grace & Co. of the United States and six French firms.[13]

Tunisia.—The Government of Tunisia is arranging financing from the World Bank to modernize old mines and develop new mines. The older mines near Gafsa are Metlaoui, Redeyef, Monlares, and M'dila. Under the 4-year plan of 1973–76, three new mines at M'rata, Sehib, and Kef Sehefera are to be opened by 1976.

U.S.S.R.—A recent U.S. Department of Agriculture study of U.S.S.R. fertilizer consumption indicated that phosphate application rates per hectare of sown area are about 30% of the rate in the United States. Although the U.S.S.R. is the second largest producer of phosphate rock in the world, with an output of 25 million tons in 1974, plans to import more phosphates to reduce the phosphorus deficiency on arable land are underway. The agreement between the U.S.S.R. and Occidental Petroleum Corp. to barter ammonia, urea, and potash for superphosphoric acid starting in 1978, and the negotiations with Morocco to secure phosphate rock for the longer term, are examples of progress to assure future phosphorus supplies.[14]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Belgium, Indonesia, and Tanzania produce phosphate rock. and South West Africa produces guano, but information is inadequate to make reliable estimates of output levels.

[2] Less than ½ unit.

[3] Estimate by International Superphosphate Manufacturers' Association, on the basis of marketable product averaging 34.8% P_2O_5; differs with data reported in the U.S.S.R. chapter of Volume III of the Minerals Yearbook, which are reported in terms of two products of differing grade.

TECHNOLOGY

The Albany Metallurgy Research Center of the Federal Bureau of Mines, Albany, Oreg., designed, assembled, and tested a phosphoric acid miniplant to demonstrate the production of phosphoric acid by direct sulfuric acid digestion of Florida land-pebble matrix. Initial tests were made with matrix from three Florida mines. Recovery of P_2O_5 exceeded 90% and gypsum crystal size was similar to that obtained in bench-scale circuit tests. The waste product was sandy and easily dewatered. Except for higher aluminum content, chemical quality of filter acid was comparable to industrial grade acid. Sulfuric acid consumption was about 8% higher processing matrix compared with processing concentrates. Studies to further investigate gypsum crystal growth and filtration rates will continue.

The Albany Metallurgy Research Center also initiated a program to study and develop methods to remove iron, aluminum, magnesium, silicon, fluorine, and other impurities from wet process phosphoric acid. Methods of accelerating sludge formation and removal were attempted and studies of the potential of ion exchange resins to extract impurities were started.

Studies were continuing at the Albany Metallurgy Research Center to develop new techniques or modify existing phosphate rock acidulation processes to increase fluorine recovery from phosphate rock, develop methods to utilize low-grade calcareous fluorspars to recover fluorine, and use waste byproducts generated by industry to recover fluorine.

The Tuscaloosa Metallurgy Research Laboratory, Federal Bureau of Mines, Tuscaloosa, Ala., continued programs to study and develop techniques to dewater phosphate slimes. The studies include gel formation in phosphate slimes, development of the moving screen method to dewater slimes, investigations of the properties of slimes, electrical conductivity measurements on the effects of reagents, scanning electron microscope work to understand the behavior of fine-particle suspensions, and development of methods to quantify the mineral content of phosphate slime wastes. In addition, the Tuscaloosa Metallurgy Research Laboratory continued to characterize samples of phosphate bearing Hawthorn Formation limestone and study beneficiation systems. A typical sample from the Hawthorn Formation may contain 5% P_2O_5. After sizing to 14 by 400 mesh, calcining, water quenching, washing, dewatering, stage grinding through 150 mesh, conditioning and flotation, a 25% P_2O_5 concentrate was produced. The P_2O_5 recovery was about one-third of the total in the sample.

The first commercial plant using an ion exchange technique, developed by Lancy Laboratories, Zelienople, Pa., to recover and regenerate concentrated phosphoric acid from waste liquor was constructed for Douglas & Lomason Co., Cleveland, Miss. At this aluminum finishing plant, the process will handle 1,500 gallons per day of waste liquor from the rinse section of the bright finishing plant. The liquor contains 22% P_2O_5. The concentrated acid will analyze about 54% P_2O_5 and be recycled to the bright finishing bath.

A test plant at Seneca Falls, N.Y., has shown that over 90% of the phosphates in municipal sewage can be removed by a biological process at about one-tenth the cost of alternative chemical methods. The PhoStrip process of Biospherics, Inc., Rockville, Md., reduced phosphate levels from 6.3 to 0.55 parts per million at a cost of about 0.2 cents per 1,000 gallons. Activated sludge bacteria were cycled through the aeration (bubbling in air) section with a pickup of phosphates and followed by an anaerobic treatment (holding in tank). The released phosphates were precipitated by chemical action.

Wet-grinding phosphate rock was proposed by Davy Powergas Inc. to save drying costs, grinding equipment, power consumption, and obtain a significant reduction in dust loadings. The process would utilize a Société de Prayon, Belgian ball mill.

Friedrich Uhde GmbH, Dortmund, West Germany, developed a process to concentrate phosphoric acid. It operates by lowering the partial pressure of the moisture over the acid with a vapor which is immiscible with water and aqueous phosphoric acid. Gasoline was recommended as an inexpensive stripping agent vapor that, flowing countercurrent in a column, adsorbs water and fluorine compounds from the acid. This mixture of water, vapor, and fluorine is condensed before entering the separator. The concentrated phosphoric acid is cooled after leaving the column.[15]

Platinum-Group Metals

By W. C. Butterman [1]

World mine production of platinum-group metals increased nearly 10% in 1974 to 5.8 million troy ounces. Most of the increment came from the Republic of South Africa, which supplied large amounts of metal to the United States and Japanese automobile manufacturers for use as emissions control catalysts. Ninety-nine percent of the world's supply of new metal was mined in three countries—the Republic of South Africa, the U.S.S.R., and Canada. Two of the metals, rhodium and iridium, were in short supply during the first 6 to 9 months of the year. Demand for the platinum-group metals remained high through the first half of 1974 but dropped in the second half as economic recession spread through the industrialized countries. Prices of platinum, palladium, rhodium, and iridium rose sharply during the year.

In the United States, mine production declined 37% to about 13,000 ounces, an amount that satisfied less than 1% of domestic demand. U.S. refinery production, including both toll and nontoll metal and derived in 1974 almost entirely from secondary materials, increased 8% to 1.4 million ounces. Imports were up 29% to 3.2 million ounces, and exports rose 33% to 800,000 ounces. Sales of platinum and palladium to the automotive industry for use in emission control devices were estimated at 500,000 ounces. Sales of platinum-group metals to other industries for traditional uses dropped 19% to 1.5 million ounces. Industry stocks rose 10% to 1.1 million ounces.

[r] Revised.

[1] The platinum group comprises six metals: Platinum, palladium, iridium, osmium, rhodium, and ruthenium.

[2] Recovered from platinum placers and as byproducts, largely from domestic copper ores.

Legislation and Government Programs.—U.S. Government inventories of platinum, palladium, and iridium remained unchanged in 1974. All three metals were substantially in excess of stockpile objectives established in 1973, but there was no

---

[1] Physical scientist, Division of Nonferrous Metals.

Congressional authorization for disposal of the excess metal. Near the end of the second quarter, the President signed a bill that retained the Environmental Protection Agency (EPA) 1975 "interim" automobile emission standards for another year through model year 1976 and authorized the agency to extend them through model year 1977, if desirable. In early 1975, EPA scheduled hearings on automotive emissions technology and its effects on fuel economy and public health.

[1] Includes 2,566 troy ounces nonstockpile-grade material.
[2] Includes 2,204 troy ounces nonstockpile-grade material.
[3] Includes 12 troy ounces nonstockpile-grade material.

DOMESTIC PRODUCTION

Domestic mine production of platinum-group metals declined 37% in 1974 to 12,657 ounces as production from an Alaskan placer deposit and byproduct output at U.S. copper refineries fell markedly. The placer deposit at Goodnews Bay, Alaska, was the only domestic deposit mined primarily for platinum-group metals.

U.S. refinery production of platinum-group metals, including both primary and secondary metal and including toll-refined, rose 8% to 1.4 million ounces. Refinery production of new or primary platinum-group metals fell 43% in 1974 as contracts for refining of foreign concentrates expired. About 60% of all primary metal was refined on a toll basis. The primary metal was derived from crude platinum and from anode slimes produced in the electrolytic refining of nickel and copper. These materials came from Alaska, the copper deposits of the Western United States, and from Canada, Norway, and the United Kingdom.

The amount of secondary metal refined on a nontoll basis increased 22% in 1974, and the output of toll-refined metal, which is typically 3 to 5 times larger, increased 7%. Thus, overall secondary metal production increased 10%.

r Revised.

CONSUMPTION AND USES

Sales of platinum-group metals, exclusive of automotive emission catalysts, decreased 19% in 1974 to 1.5 million ounces. Sales of platinum and palladium declined 10% and 27%, respectively. Sales of osmium and ruthenium countered the trend, rising 6% and 14%, respectively. Consumption of platinum and palladium in automotive emission catalysts was estimated at 300,000 ounces, with sales to the industry estimated at 500,000 ounces. Total sales of platinum-group metals to U.S. industry in 1974 were estimated at 1.98 million ounces, an 8% increase over 1973 sales. The electrical industry, for many years the largest purchaser of platinum-group metals, accounted for 28% of total sales, followed by the automotive industry (25%) and the chemical industry 22%).

Platinum sales to the automotive industry were estimated at 350,000 ounces. Platinum sales to other industries were 594,000 ounces, down 10% from the 1973 sales level. With the advent of automotive emission catalysts, the distribution of platinum among consuming industries changed in 1974. The automotive industry in a single year became the largest purchaser at 37% of total sales, followed by the chemical industry (23%), the petroleum refining industry (15%), and the electrical industry (10%). Platinum sales to the chemical, electrical, and dental-medical industries dropped 10%, 16%, 9%, respectively. Sales for miscellaneous uses showed a much steeper decline, 69%. Sales to the petroleum refining, glass, and jewelry industries increased by 13%, 3%, and 2%, respectively.

Palladium sales to the automotive industry were estimated at 150,000 ounces. Palladium sales to other industries were 736,000 ounces, 27% below the 1973 sales level. Of total sales, the electrical industry took 44%; the chemical industry, 18%; the automotive industry, 17%; and the dental-medical industry, 14%. Palladium sales to the petroleum refining industry increased about fourfold, and sales to the glass industry rose sixfold, but sales for other uses fell, as follows: Chemical, 37%; electrical, 26%; dental-medical, 8%; jewelry, 6%; and miscellaneous, 81%.

Sales of iridium decreased 26%, to about 23,000 ounces, of which 44% went to the petroleum refining industry, 32% to the chemical industry, and 12% to the electrical industry. Sales to all the principal consuming industries were below 1973 levels.

Sales of osmium increased 6% to 1,723 ounces, essentially all of which went to the chemical and dental-medical industries.

Rhodium sales dropped 16% in 1974, to about 62,000 ounces, distributed among the principal consuming industries, thus: Chemical 38%, electrical 25%, jewelry 17%, and glass 12%. The chemical industry purchased about the same amount of rhodium as in 1973, and sales to the electrical industry were up 18%. However, sales to the glass and jewelry industries were 55% and 16%, respectively, below 1973 levels.

Sales of ruthenium increased 14% to about 65,000 ounces; two-thirds went to the electrical industry, and most of the remainder, to the chemical industry. A fourfold increase in electrical industry requirements in 1974, and a halving of chemical industry requirements, reversed the distribution pattern of the past decade.

The uses for platinum-group metals in modern industry are related to their extraordinary catalytic properties, refractoriness, and resistance to chemical corrosion over a wide temperature range. The pattern of industrial applications of platinum and palladium changed significantly in 1974 with the introduction of catalytic exhaust converters on automobiles. These patterns are shown in figure 1. Catalyst manufacturers began delivering commercial quantities of emissions catalysts to automotive companies in the second quarter of the year. Typically, each vehicle required between one-twentieth and one-tenth troy ounce of platinum/palladium, the two metals being present roughly in a 2-to-1 ratio. However, one automotive company used unalloyed platinum in a catalyst for some of its vehicles. More than 90% of domestically produced automobiles were equipped with catalytic converters, as were a somewhat smaller percentage of imported automobiles.

The consumption of palladium in the U.S. electrical industry was significantly reduced in 1974, when the largest manufacturer of telephone exchange equipment began using a 60 palladium/40 silver alloy for relay contacts in place of unalloyed palladium.

Table 4.—Platinum-group metals [1] sold to consuming industries in the United States

(Troy ounces)

[e] Estimate. [r] Revised.

[1] Comprises primary and nontoll-refined secondary metals.

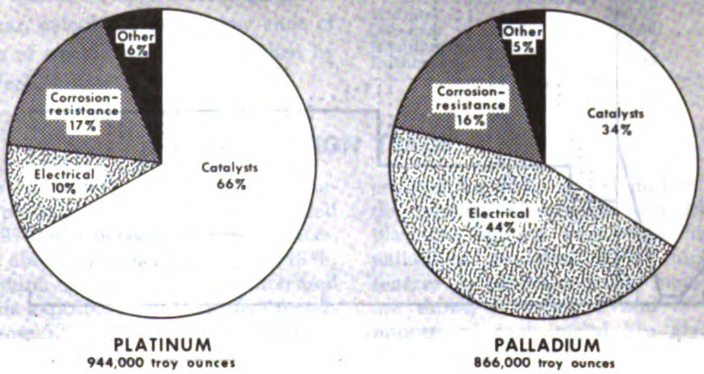

Figure 1.—Uses of platinum and palladium in 1974.

STOCKS

Stocks of platinum-group metals held by refiners, importers, and dealers increased 10% in 1974. Palladium stocks declined 1%, but stocks of the other metals increased as follows: Platinum, 23%; iridium, 17%; osmium, 166%; rhodium, 4%; and ruthenium, 10%. In addition to these stocks, there were Government stockpiles of platinum, palladium, and iridium. (The Bureau of Mines does not receive inventory data from end users of platinum-group metals; it should be noted that some industries, such as the automotive industry, may hold substantial amounts of refined metal in inventory, which are not included in Bureau stock figures.)

Table 5.—Refiner, importer, and dealer stocks of platinum-group metals in the United States, December 31 [1]

(Troy ounces)

Year	Platinum	Palladium	Iridium	Osmium	Rhodium	Ruthenium	Total
1970	291,544	332,726	13,366	1,868	47,767	22,753	710,024
1971	385,828	316,126	16,434	604	51,529	26,270	796,791
1972	426,611	405,793	14,987	82	56,967	26,413	930,853
1973	446,522	493,078	14,813	327	51,504	26,880	1,033,124
1974	549,603	486,375	17,376	869	53,533	29,621	1,137,377

[1] Includes metal in depositories of the New York Mercantile Exchange; on Dec. 27, 1974, this comprised 217,500 ounces of platinum and 12,800 ounces of palladium.

PRICES

The prices of osmium and ruthenium remained unchanged in 1974, but the prices of the other four metals rose sharply. The producers' prices, per troy ounce, increased from the beginning of the year as follows: Platinum, $158 to $190 by midyear; palladium, $84 to $150 by May; rhodium, $270 to $350 by May; and iridium, $285 to $500 by October. Dealers' prices for palladium and platinum remained above the producers' prices until the second and third quarters, respectively, then dropped below the producers' prices for the remainder of the year. Rhodium

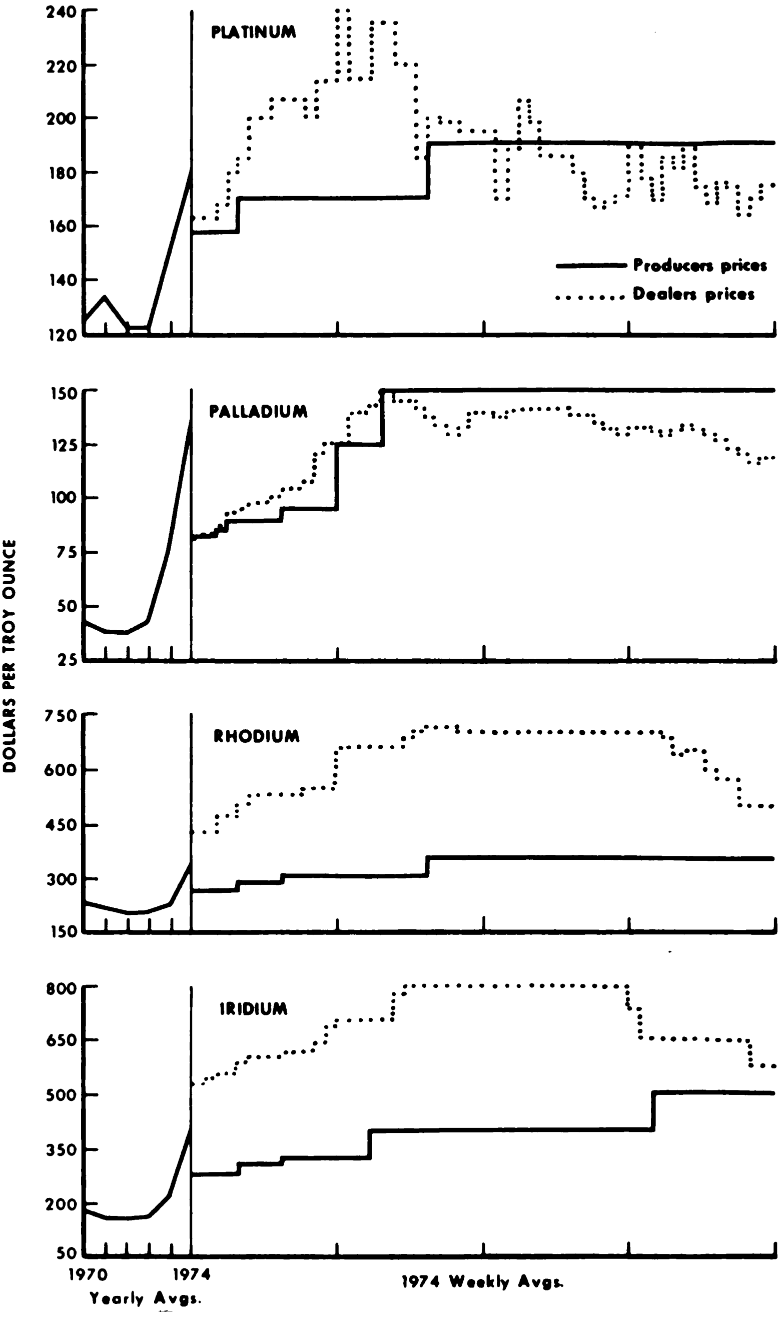

Figure 2.—Prices of four platinum-group metals.

and iridium were in short supply, and dealers' prices were high all year, about double the producers' price in the second and third quarters (fig. 2). Average prices for the year, calculated at the low ends of the ranges of weekly averages published by Metals Week, follow:

	Producer (per troy ounce)	Dealer (per troy ounce)
Platinum	$180.85	$192.37
Palladium	133.22	126.25
Iridium	390.77	699.77
Osmium	200.00	140.00
Rhodium	328.84	627.58
Ruthenium	60.00	54.73

FOREIGN TRADE

Exports of unwrought and semimanufactured platinum-group metals increased 33% in 1974, amounting to 835,754 ounces, of which about 401,000 ounces, or 48%, was platinum. Platinum exports increased 18%, while exports of the other five metals together rose 52%. The value of platinum-group metals exports increased 51% to $117 million. Three-fourths of the platinum-group metals went to four countries: Japan, 30%; West Germany, 22%; the United Kingdom, 12%; and Switzerland, 11%. Platinum alone accounted for most of the metal going to Japan and the United Kingdom but was a minor part of the total platinum-group metals going to Switzerland and West Germany.

Imports of platinum-group metals rose 29% in quantity, to 3.2 million ounces, and increased 86% in value to $503 million. Platinum and palladium each accounted for 46%, or 1.5 million ounces of the imports. Compared with 1973 levels, platinum imports were 40% higher, and palladium imports, 21% higher. The sources of platinum-group metals imports are shown in tables 7 and 8. Estimated imports of each metal are given in the following tabulation. (These figures combine the amounts explicitly stated in table 7 with estimates of the metal content of the five composite categories in that table.)

	Thousand troy ounces
Platinum	1,490
Palladium	1,498
Iridium	40
Osmium	7
Rhodium	121
Ruthenium	85
Total	3,241

WORLD REVIEW

World mine production of platinum-group metals rose 10% in 1974, to 5.8 million ounces, mainly as a result of continued expansion of capacity in the Republic of South Africa. The Republic of South Africa, the U.S.S.R., and Canada accounted for 99% of the output.

Mine production in the United States fell 37% to 12,657 ounces, which was less than 1% of industrial demand. The Johns-Manville Corp. continued exploration of the Stillwater complex in southern Montana. This assemblage of igneous rocks is believed to contain most of the U.S. resources of platinum-group metals. The results of field and laboratory tests to date suggest some possibility of future production from the area.

Placer mining in Colombia continued at the same level as in past years, yielding 27,000 ounces of platinum. Small, but significant amounts of platinum-group metals were produced as byproducts of copper and nickel refining in Japan and Finland.

Canada.—Canadian output of platinum-group metals remained about the same as in 1973. A buildup of platinum-group metals in the recovery circuits of the major producer kept production below the expected level. Platinum-group metals were byproducts of nickel-copper mining in Canada, and were produced from mines of the International Nickel Co. Inc. (INCO) and Falconbridge Nickel Mines, Ltd., in the Sudbury, Ontario, and Thompson, Manitoba, districts. A small amount came from the Manitoba properties of Dumbarton Mines Ltd. INCO's platinum-group metals-bearing concentrates were refined to metal in the United Kingdom, whereas Falconbridge's concentrates were refined in the United States after intermediate processing in Norway.

Sheridan Geophysics Ltd.[3] announced the discovery of a potentially important platinum-group metals deposit in northern Ontario at Lac des Iles, 50 miles northwest of Thunder Bay. Ore-grade platinum-group metals containing platinum and palladium in the ratio of 1 to 8 were found in two horizons that may be minable. Ore tonnages remained speculative at yearend, but exploration was being continued by Boston Bay Mines Ltd., a Sheridan Geophysics subsidiary.

South Africa, Republic of.—South Africa became the leading world producer of platinum-group metals in 1974, increasing output 20% to 2.8 million ounces. Worldwide, it accounted for nearly two-thirds of all platinum and one-fourth of the palladium mined. Except for some osmiridium recovered as a byproduct of gold mining, all of the platinum-group metals were mined as the principal products from mines in the Merensky Reef, Transvaal Province. The Reef is a very extensive and uniform formation that yields about 0.2 ounce of platinum-group metals per ton of ore, along with significant amounts of nickel and copper. South Africa is estimated to have more than two-thirds of the world's reserves of platinum-group metals. The four companies that mined platinum-group metals in 1974 are listed, with estimates of capacities and production, in the following tabulation:

Mining Journal. Platinum Property Option for Texasgulf. V. 284, No. 7292, May 23, 1975, p. 403.

Company	Estimated 1974 yearend capacity, platinum-group metals (thousand ounces)	Estimated 1974 production, platinum-group metals (thousand ounces)
Rustenburg Platinum Mines Ltd	2,100	1,775
Impala Platinum Ltd	1,630	890
Western Platinum Ltd	150	145
Atok Platinum Mines Pty., Ltd	40	25

Production of at least two of these companies was limited somewhat by the shortage of underground labor during the year.

Expansion of the Wadeville platinum-group metals refinery, owned jointly by Rustenburg Mines and Johnson, Matthey & Co. Ltd., was completed in 1974. The enlarged facility, located near Johannesburg, had a capacity of more than 1.5 million ounces of platinum-group metals.[3] During the year, Rustenburg Mines purchased the Eland Platinum Mining Co., thus acquiring a 4-mile length that had separated two sections of the Amandelbult mine, under development by Rustenburg.[4] Late in the year, Rustenburg decided to stretch its capital expenditure program by 18 months and set a new production target of 1.63 million ounces of platinum per year, to be reached by the end of 1977.

By midyear, Impala Platinum Ltd. had expanded production capacity to 850,000 ounces of platinum per year and expected to reach 950,000 ounces by yearend.[5] At midyear, the company was producing at the rate of 600,000 ounces of platinum per year. Owing to general labor shortages, brief labor disputes in the mine itself, and a mud slide that closed one shaft temporarily, the rate failed to rise significantly during the remainder of the year.

A platinum-group metals refinery with a capacity of 150,000 ounces per year was completed in the first half of 1974 by Lonhro Ltd. This facility, located at Brakpan, on the east Rand near Rustenburg, was built to process concentrates from Western Platinum Ltd.; previously, these concentrates had been refined in Norway and the United States. Western Platinum produced 139,000 ounces of platinum-group metals in 1974 compared with 109,000 ounces in 1973.[6]

Atok Platinum Mines, Pty., Ltd., doubled its production rate in 1974, bringing it to about 48,000 ounces per year of platinum-group metals by early 1975. Atok's output was processed in successive steps by Western Platinum in South Africa, and Falconbridge Nickel Mines, Ltd., in Norway.

U.S.S.R.—The U.S.S.R. remained the leading world producer of palladium in 1974, even though it fell behind the Republic of South Africa in output of total platinum-group metals. An estimated 2.5 million ounces of platinum-group metals were extracted from nickel-copper deposits in the Norilsk-Talnakh region of northwestern Siberia, and from the Petsamo-Monchegorsk region of the Kola Peninsula. A small part of the output came from the old platinum placer deposits in the central Urals. Platinum and palladium comprised about 90% of the refined metal, and the palladium/platinum ratio was estimated between 2 to 1 and 3.5 to 1. Construction continued in the Norilsk-Talnakh area on what will reportedly be the world's largest mining-metallurgical complex. A major expansion in platinum-group metals output could accompany a large expansion in nonferrous metals production that the Soviets have planned for the next few years.

e Estimate. p Preliminary. r Revised.

[1] Excludes refined platinum production from Norway, which is derived from imported raw materials, chiefly (if not wholly) of Canadian origin, in order to avoid double counting.

TECHNOLOGY

Work continued in 1974 on various aspects of automotive emissions control technology. Tests of prototype 1975 model automobiles early in the year showed that in addition to oxidizing carbon monoxide and unburned hydrocarbons satisfactorily, the new platinum/palladium catalytic converters afforded a substantial increase in fuel economy.[7] On the other hand, there were preliminary indications that the oxidation catalysts increased the emission of sulfates and sulfur acids and it was feared that large numbers of converter-equipped cars from several years production might lead at times to dangerous concentrations of sulfates in the air near roadways.[8]

Looking ahead to the stricter regulations set for 1977 cars, which required nearly an eightfold reduction in nitrogen oxides emissions, automobile manufacturers were testing reduction converters. These devices were designed to be fitted close to the exhaust manifold, upstream from the oxidation converter. Ruthenium had been found to be an effective reducing catalyst but tended to volatilize under some engine operating conditions; substantial progress in stabilization of ruthenium catalysts was reported during the year.[9] Development continued on three-way converters, in which one catalyst performs both reducing and oxidizing functions, and catalyst manufacturers were confident of the efficacy of the three-way system. However, the system requires accurate, close-coupled control of the engine fuel/air mixture, and doubts were expressed in the automotive industry about the availability of control hardware suitable for mass production.

The future of platinum-group metal automotive catalysts appeared to depend not only on the further development of catalytic systems, but also on the progress of competing systems, such as base metal catalytic systems,[10] thermal converters,[11] the lean-burn engine, and the stratified charge engine,[12] all of which were under development.

Burgeoning research on supported homogeneous catalysts was reviewed during the year. These catalysts are of a type intermediate between heterogeneous and homogeneous catalysts and are made by attaching an active metal complex to an insoluble polymer support. Most of the complexes studied to date had been rhodium compounds, but the prospects of developing other platinum-group metal catalysts of this type were considered good.[13]

Ruthenium could become important as a binder for high-temperature cemented carbides. Unlike the four cubic platinum-group metals, hexagonal ruthenium does not decompose refractory carbides. With titanium carbide, which is a significant cutting tool material, ruthenium forms a eutectic at 1,840° C, which is 400° C to 500° C above the eutectics formed with the conventional binders– nickel, cobalt, and iron.[14]

A new type of dispersion-strengthened platinum was described. Formed by the in situ oxidation of zirconium in a zirconium-platinum alloy containing only 600 ppm of zirconium, the new material has properties that are consistent and reproducible on a large scale. Good workability, a highly stable microstructure, good high-temperature strength, and creep resistance combine to make this material a potentially valuable alternative to conventional platinum alloys.[15]

Certain partially oxidized platinum complexes having semiconductive and metallic properties and anomalously high dielectric constants were described. These may be capable of development as one-dimensional metallic conductors and, ultimately, as high-temperature superconductors.[16]

It was reported that very pure metals of the lanthanide, actinide, and alkaline earth series can be prepared from their oxides by reduction in hydrogen in the presence of platinum-group metal catalysts. The platinum-group metals form intermetallic phases with the metals from the oxides; these compounds are decomposed at high temperatures to yield pure gaseous metals, which then condense to solid form.[17]

Potash

By William F. Keyes [1]

For the second successive year, potash production in the United States declined slightly, to 2.552 million short tons of K_2O equivalent in 1974. Under the stimulus of increased crop acreage and strong demand for farm products, however, consumption of potash, of which about 95% was used as fertilizer, increased 9% and surpassed 6 million tons of K_2O for the first time. U.S. production of potash was equal to 42% of apparent consumption. Exports declined 11%, and imports increased 21%, while producers' yearend stocks remained almost constant compared with 1973 but at a lower level than in previous years. Value of production increased 41%, to a new high of $159 million. Allowable potash production under prorationing by the Canadian Province of Saskatchewan was increased 5 times during the year, until it equaled the mines' nominal capacity of 8.3 million tons annually of K_2O; actual production in Canada was about 6 million tons, about 24% above the 1973 output. The Saskatchewan government announced a new potash policy involving two main elements: Increased taxation related to the characteristics of each mine and to the price of potash, and full or majority ownership by the Provincial government of all new mines. The Provincial government would also participate in expansion of capacity at existing mines.

DOMESTIC PRODUCTION

Production of marketable potash salts, in terms of K_2O content, declined 2.0% in 1974 compared with the 1973 output. The value of production soared 41%, however, because demand was stimulated by both increased cropland under cultivation and strong worldwide markets for agricultural products. Costs of production at potash mines were severely affected by the general rise in price levels, particularly for fuel, power, and explosives.

U.S. domestic production of potash, as K_2O, equaled 42% of domestic consumption in 1974, compared with 47% in 1973. The remaining 58% of consumption was met by net imports.

In New Mexico, source of 82% of U.S. production in 1974, six underground mines were operated near Carlsbad by AMAX Chemical Corp., Duval Corp., International Minerals & Chemical Corp., Kerr-McGee Corp., National Potash Co., and Potash Co. of America.

Three companies produced potash in Utah: Texasgulf, Inc., working an underground mine near Moab by solution mining; Great Salt Lake Minerals & Chemicals Corp., producing fom brines of the Great Salt Lake; and Kaiser Aluminum & Chemical Corp., treating natural brines near Wendover.

In California, potash continued to be produced from brines of Searles Lake by the American Potash Division of Kerr-McGee Corp., at Trona. Searles Lake Chemical Corp. was also considering plans to exploit Searles Lake brines for potash.

The potash (K_2O) content of ores mined in New Mexico declined to 15.5% in 1974. In 1973 it was 16.1%; a decade earlier, in 1964, the grade of crude salts mined in the State was 18.0%.

The Teledyne mine near Carlsbad, N. Mex., which was closed in 1973, was purchased by Mississippi Chemical Corp. in July 1974 and renamed Mississippi Potash Inc. This subsidiary was merged subsequently with the parent company. Plans were announced to construct new processing facilities at a cost of $50 million; these were to be in operation by 1977. Small-scale interim operation of the old plant, which was being dismantled, was planned.

International Minerals & Chemical Corp. started a $35 million expansion of production at Carlsbad. The expansion will nearly double langbeinite (a potassium-magnesium sulfate) capacity, with some expansion of muriate capacity.

In 1974, the Federal Bureau of Mines canvassed producers of potash to determine their energy consumption. The seven operating mines in the Carlsbad area in 1973, which produced 2,168,000 tons of K_2O, reported consumption in that year of 344.28 million kilowatt-hours of electricity, 1.29 million gallons of diesel fuel, 422,000 gallons of gasoline, 767,000 gallons of other liquid fuel products, and 9.23 billion cubic feet of gas. The total energy consumption was equivalent to 11.0 trillion Btu's, converting the consumption of electricity at 3,410 Btu's per kilowatt-hour. This was equivalent to 5.09 million Btu's per ton of K_2O; 86% of the energy consumed was in the form of natural gas.

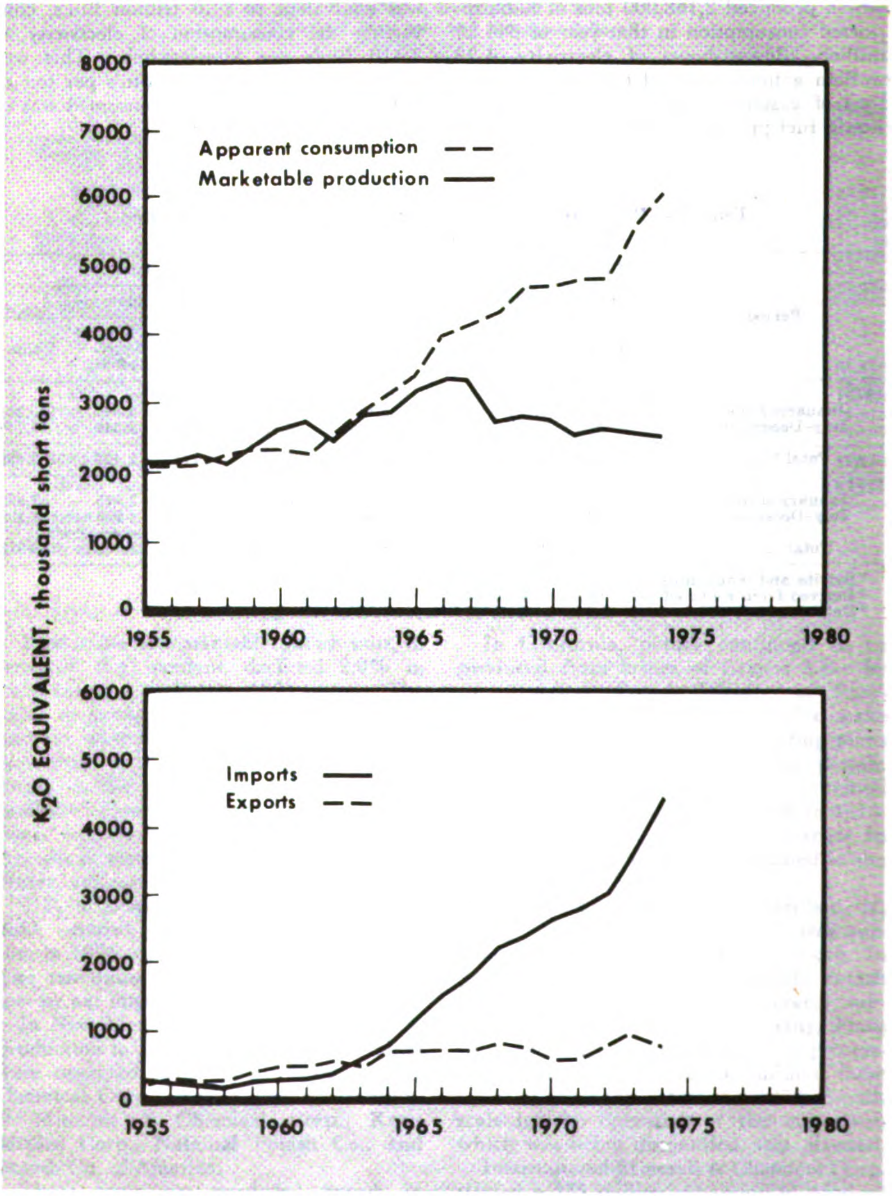

Figure 1.—Marketable production, apparent consumption, exports, and imports of potassium salts measured in K$_2$O equivalent.

CONSUMPTION AND USES

Apparent consumption of potash in the United States topped 6 million tons of K_2O for the first time in 1974; this represented a gain of 9.4% over 1973. By way of comparison, total sales of domestic and Canadian potash, according to the Potash Institute of North America, amounted to 6.04 million short tons of K_2O equivalent, including 292,000 tons (4.8%) of chemical potash sales. Imports of mined potash into the United States from overseas were reported as 121,000 tons K_2O equivalent. The north-central States of Illinois, Indiana, Iowa, Ohio, and Minnesota purchased 42% of all agricultural potash. Leading consumers of chemical potash were New York (26%), Alabama (19%), and Illinois (15%), as shown in table 4.

STOCKS

Domestic producers' stocks held steady during the year, and were 211,000 tons of K_2O at yearend 1974, compared with 206,000 tons yearend 1973. The level continued to be well below historical levels of the past two decades. Canadian producers' stocks at both onsite and offsite locations dwindled during 1974; from 530,000 tons of K_2O at yearend 1973 to 268,000 tons at yearend 1974.

Table 5.—Yearend stocks of marketable potassium salts in the United States

(Thousand short tons)

		Gross weight	K_2O equivalent
1970	13	875	454
1971	11	796	428
1972	11	878	468
1973	11	388	206
1974	10	394	211

PRICES

Prices continued an upward trend during 1974, as a result of competitive factors and inflation, and virtually doubled by yearend over levels dictated by the Cost of Living Council until October 1973. The 33.75 Canadian cents per unit floor price feature of the Saskatchewan Government's prorationing scheme was dropped completely in August, as being no longer necessary.

FOREIGN TRADE

U.S. exports declined 11% from the 1973 high. Latin America and countries around the rim of the Pacific were the principal destinations.

Potash imports rose by 21%. Imports from Canada increased 20% in 1974, and continued to supply 96% of all imports of potash. The second-place supplier, Israel, provided a little over 1% of U.S. imports in 1974, as in 1973, and the first significant imports from the U.S.S.R. were recorded.

WORLD REVIEW

Estimated world production of potash increased 7.3% in 1974.

Australia.—Unforeseen difficulties delayed the attainment of full production at the Lake McLeod potash refinery of Texada Mines, Pty. Ltd., Western Australia. The plant, an adjunct to salt production, is expected to produce 200,000 tons per year of langbeinite.

Brazil.—The terms of the agreement between Petróleo Brasileiro S.A. (PETROBRAS) and the Lume group to exploit the Sergipe potash deposits were announced. Their respective subsidiaries, Petroquisa S.A. and Comminerium Mineração S.A., each acquired 50% of the ordinary common stock of Kalium Mineração S.A., which earlier had won the competitive bidding to exploit the deposits. Some $90 million will be invested in the project. Production of potassium chloride was expected to reach 1 million tons by 1978 and 2 million tons by 1992, making Brazil self-sufficient in potash.[2]

Canada.—Prorationing quotas were raised by the Government of Saskatchewan 5 times during 1974, and in August reached the nominal capacity of the mines, 8.3 million tons per year of K_2O. Actual production reached 6 million tons during the year, and it appeared that full capacity could not be approached for some time. The minimum price feature of the prorationing scheme, which was 33.75 Canadian cents per short ton unit, was dropped completely in July. In October the Government of Saskatchewan announced a new potash policy involving two main elements: A new and additional "reserves" tax related to the characteristics of the mine (ore reserves, capacity, costs, etc.) and to the price of potash; and full or majority ownership by the Saskatchewan Government of all new mines, as well as participation in all mine expansion. The industry reacted by declaring it could not proceed with expansion plans that it had under consideration.

The Potash Co. of America continued drilling in 1974 on the potash horizon near Sussex, New Brunswick, Canada. Assessment of results was complicated by the structural complexity within the deposit. The area is approximately 20 miles from the Bay of Fundy and 40 miles by highway from St. John.

Exploration licenses were granted by the Nova Scotia Government to AMAX Exploration, Inc., and St. Joseph Exploration Co. to look for potash in the Antigonish and Stewiacke regions.

A summary of .the economic geology of New Brunswick evaporites was published.[3] Lower Carboniferous strata containing evaporites underlie a 3,000-square-mile portion of southeast New Brunswick. Sulfates (including glauberite), halite, and limestone (Albert Formation) occur within the lower part of the succession. Above the Albert Formation, and separated from it by red beds, are limestone, gypsum-anhydrite, halite, and sylvite (Windsor Group), overlain in turn by red beds. In the Windsor Group core drilling has encountered as much as 51 continuous feet of sylvinite (sylvite, KCl mixed with halite, NaCl).

Israel.—The Israeli Government's Dead Sea Works planned to increase its production of potash from 1 million tons of product per year to 1.2 million by the end of 1975, at a cost of $20 million. Further expansion to 1.5 million tons was envisioned.[4]

Italy.—All Italian potash production was under control of Industria Sali Potassici e Affini S.p.A. (ISPEA), which is owned 60.7% by Ente Minerario Siciliano (EMS), an entity of the Sicilian Government; 33.3% by Montecatini Edison S.p.A. (Montedison), a private company; and 6% by Ente Nazionale Idrocarburi (ENI), owned by the Italian Government.[5]

Laos.—The Cretaceous potash beds underlying extensive areas in Thailand are thought, from preliminary evidence, to extend into Laos on the Vientiane plain and east and south between Thakhet and Savannakhét. Plans were made by the Laos Government, with U.S. Government aid, to explore them further.

Poland.—Exploration continued on a deposit in the Bay of Puck, north of Gdynia.[6]

[6] Phosphorus and Potassium. No. 70, March–April 1974, p. 15.

Thailand.—An extensive basin containing potash deposits was investigated by the Thai Government with the cooperation of the U.S. Geological Survey. Four drillholes produced evidence of a 100-foot-thick carnallite deposit underlying 1,500 square miles centered around Udon Thani, in northern Thailand, at depths of 294 to 1,520 feet below the surface. Sylvite is present in small amounts, suggesting that economic deposits of this mineral may be found. A southern subbasin at Khorat was as yet untested, but might contain even larger reserves of potash. The basin extends into Laos around Vientiane, where a high-grade sylvite deposit was located.[7]

U.S.S.R.—Exploratory drilling continued in a fourth area of possible potash reserves. This was the Gusev deposit, near Kaliningrad on the Baltic Sea. The potash horizon is said to be up to 390 feet thick and of high grade. A mine here would be well situated to supply export markets.[8]

On May 21, 1974, the U.S. Export-Import Bank announced that it had authorized a credit of $180 million to the U.S.S.R. to assist in importing U.S. goods and exporting fertilizer raw materials to the United States. Under the terms of the overall program, the United States would export superphosphoric acid to the U.S.S.R. and import potash and nitrogen (ammonia and urea) from the U.S.S.R. The Export-Import Bank was to be involved only in financing U.S. exports of equipment, on favorable terms, to enable the U.S.S.R. to produce and ship the nitrogen materials, but its participation was also designed to encourage the overall barter agreement.[9]

United Kingdom.—The mine of Cleveland Potash, Ltd., at Boulby, Yorkshire, operated on a limited scale; full production was expected when the second shaft was completed in 1975. The delay was occasioned by problems associated with sealing off the brine-bearing Bunter Sandstone between depths of 2,000 and 3,000 feet. Both shafts reached a depth of about 3,700 feet, some 100 feet below the ore body. The ore is mined by the room-and-pillar system, and concentration is by flotation, with facilities for manufacturing, crystallization, and compaction products as well. The tailings are discharged into the sea a mile offshore through a pipeline installed in a tunnel below the seabed.[10]

TECHNOLOGY

Work at the University of Tennessee's Space Institute has demonstrated that experimentally observed absorption of potassium seed in the slag of a coal-fired magnetohydrodynamic electrical generator is much less than theoretical predictions, and will therefore not be a problem.[11]

The Federal Bureau of Mines concluded testing of flotation methods to concentrate low-grade potash salts harvested from evaporation ponds treating Great Salt Lake brines. Tests indicated that 80% of the potash in salts containing 5% to 6% potassium could be recovered by converting the kainite in the salts to schoenite in a high-$MgSO_4$ brine and floating the schoenite with medium-molecular-weight fatty acids. A report was being prepared by the Bureau, and a 10-to 15-ton-per-hour pilot plant was being constructed by the Great Salt Lake Minerals & Chemical Corp. to develop the process.

Pumice and Volcanic Cinder

By Arthur C. Meisinger [1]

Total domestic production of pumiceous materials in 1974 was 100 tons below the record quantity of 3,936,700 tons (revised) in 1973, and the value of production was a record $9.1 million. Pumice and pumicite production increased for the fourth consecutive year, and although volcanic cinder and scoria output was slightly under the record quantity (revised) of 3.1 million tons in 1973, value of production was a record $5.45 million in 1974.

The individual outputs of Arizona, California, and Oregon again led all other pumiceous material producing States. The use of pumiceous materials for road construction and maintenance and concrete admixtures and aggregates, combined, accounted for 82% of U.S. consumption in 1974. Price increases for pumice and volcanic cinder were noted in all major end uses in 1974—ranging from only a $0.05 per ton increase for railroad ballast to nearly a $5 per ton increase for landscaping.

Exports and imports of pumice in 1974 declined 6% and 5.6% in quantity, respectively, but values increased 58% and 32%, respectively, owing primarily to continued inflationary costs.

DOMESTIC PRODUCTION

The quantity of pumiceous materials (pumice, pumicite, volcanic cinder, and scoria) produced in the United States in 1974 was 3,936,600 tons, or nearly the same as the record quantity of 3,936,700 tons (revised) in 1973. Value of domestic production was a record $9.1 million in 1974 compared with the previous record value (revised) of $8.9 million in 1973.

Production of pumice and pumicite increased for the fourth consecutive year and totaled 873,000 tons valued at nearly $3.7 million. Production of volcanic cinder and scoria in 1974 was 3,064,000 tons, or only 49,000 tons under the record quantity of 3,113,000 tons (revised) produced in 1973, and was valued at a record $5.45 million. Volcanic cinder and scoria comprised 78% of the domestic output of pumiceous materials, compared with 79% in 1973.

Domestic output in 1974 came from 92 individuals, firms, and governmental agencies producing from 289 operations in 12 States, compared with 88 producers and 164 operations (revised) in 13 States in 1973. The increase of more than 100 operations over those in 1973 was directly related to increased demand for volcanic cinder for use on roads in National Forest lands in several western States.

The principal producing States in 1974, in order of output, were Oregon, California, and Arizona, and their combined output of pumiceous materials accounted for 68% of the national total. Other States with significant output were Hawaii, Nevada, and New Mexico. Of the six leading States, three (California, Hawaii, and New Mexico) showed production increases in 1974, and three (Arizona, Nevada, and Oregon) had declines in output.

California led all the producing States in 1974 with 130 active operations, followed by Arizona with 58, Oregon with 39, and Hawaii with 27. Volcanic cinder was produced in 11 of the 12 States and in American Samoa.

CONSUMPTION AND USES

The use of pumiceous materials for road construction and maintenance and concrete admixtures and aggregates, combined, accounted for 82% of U.S. consumption in 1974, compared with 80% (revised) in 1973. Of the remainder, railroad ballast comprised nearly 11%; abrasives and other uses, 4%; and landscaping, 3%. Compared with consumption in 1973, use in road construction increased 6%, and abrasives and other uses increased 35%; however, the other major end-use categories showed declines of 17% for railroad ballast, 27% for landscaping, but only 3% for concrete aggregate and admixture.

[2] Data may not add to totals shown because of independent rounding.

PRICES

The average value for crude pumice, pumicite, and volcanic cinder sold and used increased from $0.93 per ton (revised) in 1973 to $1.10 per ton in 1974. The average value for prepared material increased also—from $3.60 per ton in 1973 to $3.72 per ton. The weighted average value of pumiceous materials was $2.32 per ton compared with $2.26 per ton (revised) in 1973.

Increases in average prices for all major end uses of pumiceous materials (except "Other uses") were reported in 1974. Compared with 1973, the average price per ton for pumice and volcanic cinder used in cleaning and scouring compounds in 1974 was $31, a $3.95 increase; for concrete admixtures and aggregates, $2.62, a $0.39 increase; for landscaping, $9.97, a $4.94 increase; for railroad ballast, $1.10, a $0.05 increase; and for road construction, $1.31, a $0.09 increase. The category of other uses declined in average price from $15.02 per ton in 1973 to $6.40 per ton.

American Paint & Coatings Journal reported no change in the prices for pumice stone in 1974. Quoted prices at yearend were as follows per pound, bagged f.o.b. New York or Chicago: Powdered, $0.0445 to $0.08, and lump, $0.0665 to $0.09.

Price quotations for pumice in Chemical Marketing Reporter, which were changed in May 1973, remained in effect throughout 1974 and were as follows: Domestic grades, bagged in ton lots, fine, $0.0765 to $0.1140 per pound; medium, $0.1160 per pound; coarse, $0.094 per pound; imported (Italian) silk-screened, bagged in ton lots, fine, $138 per ton; medium, $150 per ton; and coarse, $140 per ton. Price of imported small and large lump size was quoted at $275 per ton.

FOREIGN TRADE

Exports of pumice, pumicite, and volcanic cinder (scoria) in 1974 declined 6% to 2,911 tons, from the record quantity of 3,095 tons in 1973. West Germany received 2,184 tons, or 75% of the total quantity exported to 16 countries in 1974.

Pumice imports in 1974 declined for the second straight year; however, the quantity was only 5.6% less than that of 1973, compared with the 48% decline in quantity from 1972 to 1973. The value of imports in 1974 increased 32% over that of 1973. Total value of all import classes, primarily from Italy and Greece, was $1.52 million in 1974 compared with $1.15 million in 1973.

Imported pumice used in the manufacture of concrete masonry products declined 7% from that of 1973, and imports classed as wholly or partly manufactured declined 21%. However, crude or unmanufactured imports of pumice from Italy increased 67% from 5,026 tons in 1973 to 8,415 tons.

Pumice stone, TSUS No. 519.05, for use in concrete products continued to be admitted into the United States duty free. Duties for other products at yearend were unchanged from 1973 as follows: TSUS No. 519.11, crude or crushed pumice, valued not over $15 per ton, 0.02 cent per pound; TSUS No. 519.14, crude or crushed pumice, valued over $15 per ton, 0.04 cent per pound; TSUS No. 519.31, in grains or ground, pulverized or refined, 0.17 cent per pound; and TSUS Nos. 519.93 and 523.61, millstones, abrasive wheels, and abrasive articles, n.s.p.f. and articles, n.s.p.f., 7% ad valorem.

Rare-Earth Minerals and Metals

By James H. Jolly [1]

World production of rare-earth oxide (REO) contained in concentrate increased slightly in 1974, despite the continuing decline in world monazite output. The increase was due to record production of bastnaesite at Mountain Pass, Calif., by Molycorp Inc., which produced more than 70% of the total world REO output. Monazite production continued to be adversely affected by decreasing monazite contents at some heavy mineral mines, rising costs, and plant problems. Production of rare-earth compounds and metals was adequate to meet market demand. Prices for rare-earth concentrates and compounds increased selectively by 10% to 40%. Further price increases were expected in 1975.

The domestic rare-earth industry in 1974 was highlighted by record production, development of a new placer deposit from which byproduct monazite was recovered, expansion of production facilities, and a high level of shipments and exports of rare-earth materials. The Rare Earth Metals Co. of America (REMCOA) successfully completed pilot plant tests using a Bureau of Mines-developed process to produce mischmetal and planned to construct a 125-ton-yer-year demonstration unit. The overall end-use consumption pattern of rare earths was similar to that of 1973. Petroleum catalysts continued to be the major consumer. The second largest use was as additives in iron and steel production. This use remained at the 1973 level despite reduced demand of steel by the automotive industry.

Legislation and Government Programs.—At the end of 1974, the General Services Administration (GSA) held a total of 9,124 short tons (dry) of REO equivalent in the national (7,198 tons) and supplemental (1,926 tons) stockpiles. Disposals for the year amounted to 2,553 tons of contained REO. The Y_2O_3 stockpile remained unchanged at 237 pounds. The rare-earth elements were removed from the list of strategic and critical materials in March 1971 and were authorized for orderly disposal to industry.

During 1974, the Office of Minerals Exploration (OME), U.S. Geological Survey, continued financial assistance of 50% of approved costs for exploration for rare-earth and yttrium resources.

DOMESTIC PRODUCTION

Concentrate.—In 1974, domestic production of REO in concentrate exceeded the 1973 record high by 11.2%. More than 90% of production was in the form of bastnaesite; the remainder was in the form of monazite.

The Mountain Pass, Calif., operation of Molycorp, Inc., produced about 21,950 tons of REO contained in bastnaesite concentrate in 1974, compared with about 19,350 tons in 1973.[2] Molycorp completed a 50% expansion of its milling and flotation facilities, to 30,000 tons REO annually, in January. However, because of delays in delivery of auxiliary equipment and shortages of chemical reagents, the new plant did not operate near its design capacity until the fourth quarter.

Titanium Enterprises, jointly owned by American Cyanamid Co. and Union Camp Corp., continued to recover monazite as a byproduct of mining Pleistocene beach sands for titanium minerals and zircon near Green Cove Springs, Fla. Monazite output, which declined in 1974, was adversely affected by mining difficulties and production losses caused by the commissioning of a new heavier dredge.

---

[1] Physical scientist. Division of Nonferrous Metals.

[2] Molycorp Inc. 1974 Annual Report. Mar. 3, 1975, 12 pp.

Monazite production by Humphreys Mining Co. also decreased in 1974 owing to the exhaustion of ore reserves at midyear at its beach sand deposit near Folkston, Ga. The company moved its dredging operation to a new beach sand deposit in Florida, a few miles south of the former deposit. Production at the new deposit began in November. The heavy mineral concentrate was trucked to the existing Folkston plant for processing.

Ethyl Corp. conducted tests to determine the feasibility of mining and recovering heavy minerals, including monazite, from the McNairy Formation near Paris Landing, Tenn. The company, which reportedly has about 2,000 acres under lease, planned to mine the formation by dredging methods if the tests were successful.[3]

Compounds and Metals.—Molycorp and the Davison Div. of W. R. Grace & Co., Chattanooga, Tenn., were the only volume processors and producers of rare-earth compounds in 1974. Molycorp, with processing plants at Mountain Pass, Calif., Louviers, Colo., and York, Pa., continued to be the principal domestic producer. Production was up slightly over that of 1973, and sales, including concentrates, were a record $23.1 million. The company completed expansion of chemical processing facilities at the Louviers and York plants in 1974 and expected to complete further additions to the milling and processing facilities at Mountain Pass in 1975.

High-purity rare-earth oxides and compounds were produced by Molycorp; Davison; Research Chemicals Div., Nucor Corp., Phoenix, Ariz.; Atomergic Chemetals Co., Div. of Gallard-Schlesinger Chemical Manufacturing Corp., Carle Place, N.Y.; and Transelco Inc., Penn Yan, N.Y. Molycorp, Research Chemicals, and Atomergic produced yttrium oxide and/or metal during the year. Significant quantities of high-purity rare-earth compounds were also sold during 1974 from the stocks of two former rare earth processors—the Lindsay Rare Earths Div. of Kerr-McGee Corp., West Chicago, Ill., and Michigan Chemical Corp., St. Louis, Mich.

Mischmetal was produced by Ronson Metals Corp., Newark, N.J., and Reaction Metals Inc., West Pittsburgh, Pa., a subsidiary of Rare Earth Industries. Ronson increased its production capacity in 1974 by adding additional electrowinning cells of new design. Mischmetal shipments increased slightly over those of 1973; however, production decreased.

REMCOA, owned 51% by Aluminum Co. of America (Alcoa) and 49% by Molycorp, successfully completed pilot electrolytic cell tests to produce rare-earth metals from bastnaesite concentrate. REMCOA planned to construct a 20,000-ampere production demonstration unit with a 125-ton annual capacity at Alcoa's Arnold, Pa., research facility. Additional production cells were planned for 1976 at a location to be determined.

Rare-earth ferrosilicon alloys, consumed primarily by the iron and steel industry in the United States and Canada, were produced by four companies: Foote Mineral Company, Ohio Ferro-Alloys Corp., American Metallurgical Products Co., Inc., and Union Carbide Corp. Production and shipments were considerably higher than in 1973.

Raytheon Co., Waltham, Mass., expanded its rare earth-cobalt magnet production facilities by installing a large, high-volume sintering furnace.[4] In 1974 the company marketed two new magnet materials, samarium-praseodymium-cobalt and mischmetal-cobalt. Other domestic producers of rare earth-cobalt magnets were Crucible Magnetics Div. of Colt Industries Inc., Elizabethtown, Ky.; Spectra-Flux Corp., Watsonville, Calif.; Electron-Energy Corp., Landisville, Pa.; and Hitachi Magnetics Corp., Edmore, Mich.

[4] American Metal Market. Raytheon Installs Sintering Furnace To Make Rare-Earth Cobalt Magnets. V. 81, No. 45, Mar. 6, 1974, p. 5.

CONSUMPTION AND USES

Domestic rare-earth processors consumed an estimated 18,200 tons of REO contained in mineral concentrate in 1974 Bastnaesite consumption increased almost 7%, whereas monazite consumption decreased about 20%. Shipments of rare-earth and yttrium products from processing plants to domestic end use consumers were about 10,500 tons (in terms of REO), valued at about $26 million.

The approximate quantitative percentage distribution of rare-earth and yttrium consumption by end use, based on information supplied by primary processors and certain consumers, was as follows: Petroleum cracking catalysts, 44%; metallurgical, including nodular iron and steel, other alloys and mischmetal, 34%; ceramics and glass, 17%; and miscellaneous, including electrical, arc carbons, and research, 5%. Shipments of high-purity rare-earth and yttrium oxides and metals, although representing less than 1% of the total weight of shipments, accounted for about 25% of value shipped.

The manufacture of petroleum-cracking catalysts containing rare-earth zeolite as the active compound continued to be the largest use. Metallurgical usage remained at the 1973 level although certain applications, such as in ductile iron, continued to increase rapidly. The decline in automobile production in 1974 reduced rare-earth usage in the production of high-strength, low-alloy (HSLA) sheet and slowed research and development of HSLA alloys by the automotive industry. Mischmetal and rare-earth silicides were the forms most commonly used to add rare earths to ductile iron and steel. The rare earths promote ductility, improve impact and yield strength and formability, and are useful for the deoxidation and desulfurization of continuously cast and HSLA steel.

The production of lighter and striker flints continued to be a major consumer of mischmetal. Other rare-earth alloys and metals were used in the production of high-temperature alloys and superalloys and nuclear reactor control rods.

Besides the well-known use of cerium oxide for polishing plate glass, eyeglasses, television tubes, and camera lenses, a major and increasing use worldwide of cerium oxide was as a decolorizing agent in refining clear glass. Other rare-earth oxides—praseodymium, erbium, holmium, and neodymium—exhibit strong absorption of light and were used as colorants in glass. Lanthanum oxide increases the refractive quality of camera lenses.

Yttrium oxide and europium oxide were important phosphor materials in color television tubes. Terbium-activated gadolinium or lanthanum oxysulfide phosphors are increasingly used to intensify X-ray images; patients receive less X-ray dosage and images are brighter. Crystals of yttrium (or gadolinium)-aluminium (or iron) garnet (YAG) were used as microwave filters and control devices. The garnets, when doped with small quantities of neodymium or erbium, were used as lasers. YAG crystals have the appearance of diamond and are used as gem stones.

Rare-earth oxides and fluorides added to carbon arc electrodes emit a brilliant white light that is necessary for searchlights and for color motion picture photography and projection.

High-energy permanent magnets composed of rare earth-cobalt alloys consumed an estimated 5,000 pounds of rare earths, mostly samarium and mischmetal, in 1974. These magnets, which are two to three times more powerful than previous compositions, were used mainly in electric wristwatches, traveling wave tubes, and small electric motors and generators.

STOCKS

Bastnaesite concentrate stocks held by the principal producer and five other chemical processors at yearend increased 140%; monazite concentrate held by the two producers and two processing companies increased about 13%. Mischmetal stocks held by two principal producers and stocks of high-purity metals held by three firms remained at the 1973 level.

PRICES

Prices for domestic monazite remained stable during the year, whereas prices of foreign-produced monazite rose about 6% because of continued strong demand and reduced production. The average price per metric ton of Australian monazite (minimum 60% REO plus ThO_2), quoted in Metal Bulletin (London), increased from $200 f.o.b. and $215 c.i.f. at midyear to $215 and $228, respectively. The declared value of imported monazite concentrate from Malaysia and Thailand averaged $152 per short ton in 1974, 26% higher than in 1973. Malaysian xenotime concentrate with a minimum of 25% yttrium oxide content, as quoted in Industrial Minerals (London), remained unchanged at $3 to $5 per pound.

Unleached, leached, and calcined bastnaesite containing 55% to 60%, 68% to 72%, and 85% to 90% REO increased about 5 cents per pound REO in 1974 to 36, 41, and 48 cents, respectively, f.o.b. Mountain Pass or Nipton, Calif., in 100-pound paper bags or 55-gallon steel drums in truckload or carload lots.

Rare-earth oxide compound prices, in a downtrend since 1965, increased in 1974; further price increases were expected on many items in 1975, owing to price hikes for concentrates and higher processing costs. Prices per pound f.o.b. plant, for certain rare-earth compounds, also increased significantly; quoted prices at yearend were as follows: Mixed rare-earth oxides, 97% REO, $1.75 under 500 pounds decreasing to $1.45 for lots over 5 tons; chlorides, $0.45; carbonates, $1.15; fluorides, 84% REO, $1.27; and lanthanum-RE hydrate, $0.48.

Prices for optical-grade ceric oxide in lot sizes of 50 pounds or more delivered in bags or drums were at $2.25 per pound, up 25 cents. Quotations on cerium hydrate, 90% CeO_2 of total REO, increased from $1.50 per pound to $2, whereas 95% to 98% CeO_2 cerium hydrate rose 50 cents per pound to $2.05.

Quoted prices on 1-pound ingots in 50- to 100-pound lots of 97% didymium and cerium-free mischmetal remained at $15 and $5, respectively, f.o.b. plant. Mischmetal 99.8%, was quoted at $3.25 per pound, same basis. Ferrosilicon, containing 30% rare-earth metal, was quoted at $2.15 per pound (contained rare-earth metal). Rare earths for magnet use, 99% purity in 10- to 100-pound amounts, as quoted in American Metal Market were as follows, per pound: Cerium, $18; lanthanum, $27.50; praseodymium, $62.50; and samarium, $75.

Table 1.—Prices of high-purity oxides, salts, and metals in 1974[1]

(Dollars per pound)

[1] Research Chemicals, Nucor Corp., f.o.b. Phoenix, Ariz. Other producers may have different prices on some items.

[2] Minimum 99.9% purity, more than 1 pound.

[3] Minimum 99.9% purity, more than 1 pound; includes chlorides, nitrates, sulfates, oxalates, and acetates.

[4] Minimum 1 pound, ingot form.

[5] Price increased over that of 1973.

FOREIGN TRADE

According to the sole domestic producer, Molycorp, exports of bastnaesite concentrate were about 4,700 tons contained REO, slightly lower than those of 1973.

Exports of ferrocerium and other pyrophoric alloys to Sweden, Canada, Thailand, Australia, and 24 other countries increased 75%, totaling 192,144 pounds valued at $503,226. The average unit value of $2.62 per pound was up slightly over that of 1973.

Exports of compounds and mixtures of rare-earth metals, including yttrium and scandium, increased from 4,047,741 pounds valued at $4,592,374 in 1973 to 4,987,799 pounds valued at $6,644,533 in 1974. The large increase in value was due mainly to shipments of higher priced rare-earth compounds to West Germany and Italy.

Imports of monazite decreased substantially from those of 1973, although shipments from Thailand tripled, reaching 336 tons in 1974.

Cerium oxide imports, predominately from West Germany and France, totaled 31,390 pounds, valued at $100,977, compared with 11,716 pounds, valued at $22,826, in 1973. Other cerium compounds, n.s.p.f., mainly from France and Austria totaled 35,402 pounds, valued at $73,736, a 114% increase in quantity, but had the same unit value as in 1973.

Table 2.—U.S. imports for consumption of monazite, by country

Country	1970		1971		1972		1973		1974

[e] Estimate. XX Not applicable.

Table 3.—U.S. imports for consumption of rare-earth metals

(Including scandium and yttrium)

Country	1972		1973		1974	
	Pounds	Value	Pounds	Value	Pounds	Value
Germany, West	--	--	531	$4,322	641	$27,827
Japan	2,465	$5,585	--	--	--	--
Mexico	--	--	--	--	112	2,331
Norway	22	535	--	--	--	--
U.S.S.R.	2,650	51,870	11,446	200,349	7,785	157.957
United Kingdom	23	7.957	7	5,655	4	5,235
Total	5,160	65.947	11,984	210,326	8,542	193,350

Imports of rare-earth metals decreased 29% to 8,542 pounds in 1974, but the value of metal imports fell only 8%, owing mainly to higher prices.

Imports of ferrocerium and other pyrophoric alloys increased to 57,519 pounds, valued at $238,110, compared with 1973 receipts of 38,206 pounds, valued at $126,631. France supplied 73% of total shipments, valued at $165,901, followed by Japan with 23%, valued at $54,453. Other suppliers were the United Kingdom, Austria, and Singapore. No mischmetal was imported during 1974.

The tariffs on rare-earth metals and compounds were the same as in 1973. The tariff was 15% ad valorem on cerium oxide and chloride, $0.50 per pound on rare-earth alloys and mischmetal, $0.50 per pound plus 6% ad valorem on ferrocerium and other pyrophoric alloys, and 5% ad valorem on rare-earth metals and yttrium. Rare-earth ores and concentrates remained duty-free.

WORLD REVIEW

Australia.—Production of monazite continued to decline owing to leaner monazite contents in the ore, rising costs, and plant problems. According to the Rutile & Zircon Development Assoc., Ltd., monazite production by member companies, in short tons, in 1974 was as follows:

State	1972	1973	1974
New South Wales	1,604	1,076	1,071
Queensland	121	64	30
Western Australia	3,056	3,087	2,550
Total	4,781	4,227	3,651

Mary Kathleen Uranium Ltd. planned to construct a large-scale pilot plant early in 1976 to extract rare earths during the processing of its uranium ores. Commercial rare-earth production, having a value of about $4 million annually, was expected in 2 or 3 years, depending on the outcome of pilot tests.

[e] Estimate [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Indonesia and North Korea produce monazite, but available information is inadequate to make reliable estimates of output levels.

[2] Exports.

Brazil.—Mineral Deposits Ltd., an Australian firm, and the Comissão Nacional de Energia Nuclear, the Government nuclear authority, planned a joint exploration venture to prospect for heavy mineral sands in Brazil. If deposits are located, a joint company was to be established to mine and market ilmenite, rutile, zircon, and monazite.[5]

Canada.—In 1974, Denison Mines, Ltd., which resumed recovery of yttrium from waste uranium liquors in 1973, produced 86,788 pounds of yttrium oxide in a yttrium-rare earth concentrate. The entire production was exported.

Finland.—Kemira Oy was exploring a large rare-earth (0.4%) fluorapatite deposit as possible feed for the fertilizer complex at Siilinjarvi, in east-central Finland. A decision to go ahead with the project, including whether or not to recover rare earths, was expected in 1976 with full production by 1978.[6]

India.—India Rare Earths Ltd. (IRE), the state-owned company that mines and processes domestic monazite, planned to construct a rare-earth plant to process monazite at Gopalpur in Orissa, northeast India. The new capacity will be in addition to that at IRE's Alwaye plant in Kerala State.[7]

Malawi.—Lonrho Ltd. established a pilot plant to evaluate and beneficiate monazite and strontianite deposits at Kangankunde Hill. The deposit has inferred reserves of more than 15,000 tons of low-thorium monazite.

Malaysia.—Malaysian Rare Earth Corp. (MRE), a joint venture of Mitsubishi Chemical Ltd. and Reh Minerals Ltd., has been formed to process xenotime extracted from tin tailings. MRE anticipates that the operation will account for about half the world demand for yttrium when completed.

Norway.—In June, A/S Megon & Co. began full production of high-purity yttrium oxide at new facilities at Kjeller. The plant has a capacity of 30 to 50 tons per year and is designed to produce purities of 99.99999% Y_2O_3. Production has come from imported xenotime and byproduct concentrates from rare-earth processing plants in Japan and the United Kingdom, but by mid-1975, the plant was scheduled to use only Malaysian and Australian xenotime. To assure supplies, Megon was participating in a joint venture with Malaysian interests to construct and operate a 30-ton-per-year xenotime concentration plant near Kuala Lampur.[8]

[7] Industrial Minerals. A New REO Plant at Gopalpur. No. 86, November 1974, p. 26.

Sri Lanka.—A survey of the Pulmoddai beach-sand deposit by the Sri Lanka Geological Survey Department has established reserves of more than 3.2 million tons of heavy minerals sands, of which about 0.4% is monazite.[9]

TECHNOLOGY

The hydrogen-storage ability of lanthanum-nickel ($LaNi_5$) intermetallic alloy attracted considerable attention in 1974 because of the potential use of hydrogen as an alternate energy source. Because the alloy can absorb hydrogen at about twice the density of liquid hydrogen in one-third the space, uses in powerplant load-leveling systems, industrial supply, and automobiles were being considered.[10] Possible nonfuel uses based on hydrogen desorption and absorption factors include compressors and nickel-hydrogen batteries[11] and controllable home-heating sources using solar energy.[12]

The Bureau of Mines was investigating the hydrogen absorption characteristics of mischmetal and other rare-earth metals, nickel, and cobalt intermetallics. Preliminary results indicate that, of the alloys tested, only $LaNi_5$ and $LaCo_5$ exhibited significant absorption characteristics.

Rare-earth β-diketoenolates were tested as antiknock agents in motor fuels.[13] Preliminary results indicated they were as effective or better than tetraethyl lead in some applications. In addition, combustion products of the additive were effective in reducing noxious hydrocarbon emissions.

More efficient removal of objectional organic emissions in certain chemical processes, including automobile exhaust systems, using a new family of $LaCoO_3$ catalysts may be possible.[14] The catalystic properties of the compound can be modified by replacing a fraction of the lanthanum and zirconium, tin, or thorium to alter structural defects. Researchers at Bell Laboratories are using similar methods to modify the properties of rare earth-lead manganites, also a potential automotive exhaust catalyst.

Laser fusion technology was advanced when Battelle Columbus Laboratories produced 1,400 joules of laser energy in a 3.5-nanosecond pulse using a 12-beam, neodymium-doped glass laser that has an overall potential of 2,500 to 3,000 joules.[15] The experimental results indicated that a short-pulsed laser with an energy greater than one kilojoule can be constructed and used for laser plasma studies without causing damage to the system or premature target destruction. One report indicated that a demonstration laser fusion power reactor might be on-line by the mid-1990's.[16]

Research on rare-earth additives in steelmaking continued to be directed toward improving addition techniques to control sulfide shape.[17] In another study, prediction of the behavior of rare-earth elements in steel by using available thermodynamic and phase equilibria data was discussed.[18]

A rare-earth, ferroelectric ceramic (7% lanthanum in lead titanite) developed by Sandia Laboratories may boost computer holography by improving image storage. When light is projected through a photographic negative and voltage is applied, the ceramic deforms into thousands of retrievable microscopic depressions that are related to the light intensity.

The addition of small amounts of yttrium to such superalloys as Fe-Cr and

Ni-Cr increases oxidation resistance and operating temperature. Several new alloys for use in jet engines and in high-temperature gas turbines were reported.[19] In another development, an improved Ni-Cr-Al-Y alloy was designed for use as a protective coating on turbine blades.[20] The alloy, which is vapor deposited, provides better oxidation and corrosion resistance than aluminide coatings and lasts about 4 times longer.

The Eleventh Rare Earth Research Conference was held at Traverse City, Mich., in October. The program covered all phases of current rare-earth research and development and included sessions on bi-organic chemistry, coordination chemistry, magnetics, metal physics and metallurgy, solid state science, spectroscopy, and industrial applications.[21]

Rhenium

By Larry J. Alverson [1]

Domestic rhenium production decreased in 1974 but was more than adequate to meet the slightly increased demand from all end use sectors. The prices for rhenium and its compounds continued to decline but at a less rapid pace than in previous years; stocks continued to increase. Imports of metal declined precipitously while imports of ammonium perrhenate increased slightly, resulting in an overall decrease in total rhenium imports of about 25%. Bimetallic platinum-rhenium catalysts used in petroleum refining continued to represent the major use for rhenium in this country and worldwide.

Table 1.—Salient rhenium statistics

Stocks, Dec. 31 [e]	6,200	9,700	13,000	20,000	26,000

[e] Estimate. [r] Revised.

DOMESTIC PRODUCTION

Production of rhenium, a byproduct recovered primarily from molybdenite (MoS_2) associated with southwestern United States, Chilean and Canadian porphyry copper ores, decreased in 1974 to an estimated 6,700 pounds, contained in ammonium perrhenate. Cleveland Refractory Metals (CRM), a subsidiary of Kennecott Copper Corp., continued to be the leading rhenium producer in the United States. CRM processed domestic MoS_2 concentrate from operations of Kennecott and Magma Copper Co., as well as concentrates from Chilean and other domestic sources, at its Garfield, Utah, roasting facility.

M&R Refractory Metals, Inc., at its Winslow, N.J., plant produced rhenium salts for Engelhard Minerals & Chemicals Corp. on a "toll" or contract conversion basis, from MoS_2 recovered at Magma's San Manuel porphyry copper mine. Shattuck Chemical Co., Denver, Colo., a division of Engelhard Minerals & Chemicals Corp., recovered rhenium salts from Arizona molybdenite concentrate. Molybdenum Corp. of America recovered rhenium salts from MoS_2 concentrate from Arizona porphyry copper ores and primary molybdenite from the Questa molybdenum mine in New Mexico.

Newmont Exploration Ltd., a subsidiary of Newmont Mining Corp., continued its investigations into a method for the economical recovery of rhenium from Magma Copper Co.'s Arizona molybdenite concentrates.

Porphyry copper deposits in Canada, Chile, Peru, the United States, and the U.S.S.R. are the major or potential worldwide sources of rhenium. Rhenium recovery facilities outside of the U.S. exist in Chile, Belgium, Bulgaria, France, Sweden, the United Kingdom, the

---

[1] Industry economist, Division of Ferrous Metals.

U.S.S.R., and East and West Germany. The United States operated at about 50% of rhenium production capacity in 1974.

CONSUMPTION AND USES

Approximately 75% of the estimated 1974 rhenium consumption of 4,500 pounds was used in bimetallic platinum-rhenium catalysts for refining low-lead and no-lead high-octane gasoline. Bimetallic catalysts continued to capture more catalytic-reforming capacity in semi-regenerative, cyclic, and other reformers, with platinum-rhenium catalysts representing an important part of this activity. About 44% of this country's reforming capacity is accounted for by bimetallic catalysts, compared with 30% just 3 years ago.[3] Platinum-rhenium's percentage has grown also, and now stands at about 60% to 70% of total bimetallic catalyst capacity, or 25% to 30% of total domestic reforming capacity.

Older refineries continued to make conversions from straight platinum catalysts to bimetallic ones, such as platinum-rhenium catalysts. This, in conjunction with new reformers added in 1974, brought the net additional reforming capacity to 164,000 barrels per day. The Arkansas City, Kans., refinery of Apco Oil Corp. was increasing its catalytic reforming capacity by 10,000 barrels per day and was to employ Universal Oil Products Co.'s R–16G platinum-rhenium catalyst. Completion was expected in the summer of 1975. Standard Oil Co. of California (SOCAL) planned to complete another 25,000-barrel-per-day Rheniformer at its Richmond, Calif., refinery by late 1975. SOCAL is also installing 25,000-barrel-per-day Rheniformers at its Perth Amboy, N.J., and Pascagoula, Miss., refineries. The California and New Jersey units will have two stages while the Mississippi unit will have a single stage. Each of these units will use 400 to 500 pounds of rhenium.

The remaining 25% of estimated domestic rhenium consumption was in high-temperature thermocouples, electronic devices, X-ray tubes and targets, electrical contacts, vacuum tube and flashbulb filaments, heating elements, metallic coatings, and electromagnets.

Rhenium is being evaluated as an alloying material with nickel for use in jet engine turbine blades. If this use proves successful, it would provide a substantial new outlet for the depressed rhenium market. Tungsten-rhenium thermocouples experienced an increase in demand during 1974. One such thermocouple, tungsten-3% rhenium versus tungsten-25% rhenium, with proper insulating materials, is used continuously to 2,400°C and intermittently as bare wire up to 2,800°C for temperature measurement in clean inert atmospheres, hydrogen, vacuum, and nuclear environments.

PRICES

The price for rhenium metal powder during the year ranged from about $675 to $625 per pound, depending on quantity, decreasing toward $625 by yearend. The price for perrhenic acid, a starting material in catalytic applications, ranged from about $625 to $600 per pound, depending on quantity, trending toward $600 in the second half of the year. These price decreases reflected the soft nature of the domestic rhenium market, due principally to the lack of new reforming units that utilize platinum-rhenium catalysts.

FOREIGN TRADE

Imports for consumption of unwrought rhenium metal powder, waste, and scrap dropped precipitously during 1974, totaling only 40 pounds valued at $27,734. The imported unwrought rhenium metal was recovered in the supplying country from byproduct molybdenite believed to have come from porphyry copper ores mined in Canada, Chile, and Peru. The average price of the metal imports was $693 per pound, all coming from West Germany.

---

[3] The Oil and Gas Journal. Building by Small Refiners Boosts U.S. Refining Total. V. 73, No. 12, Mar. 24, 1975, pp. 13–16.

Estimated imports of ammonium perrhenate (NH_4ReO_4), from Chile, Sweden, and West Germany increased 8% during the year to an estimated 3,287 pounds of contained rhenium valued at $1,805,000. Substantial quantities of ammonium perrhenate totaling an estimated 1,842 pounds of contained rhenium valued at $1,066,066 were also imported from Chile into bonded warehouses during 1974. This material was purchased in compliance with an existing long-term contract, and was imported under the basket classification "Ammonium compounds, not specifically provided for (TSUS 417.44)."

Table 2.—U.S. imports for consumption of rhenium metal [1] (including scrap), by country

r Revised.

[1] Figures are derived from the basket category "Ammonium compounds not specifically provided for (TSUS 417.44)."

[2] The 1,786 pounds reported to the Bureau of Mines as rhenium metal was actually ammonium perrhenate having a rhenium content of 1,232 pounds. The 1,232 pounds was entered in this table with other ammonium perrhenate imports. The totals have been adjusted by the Bureau of Mines to reflect a more accurate picture of rhenium imports in 1974.

The import duty on rhenium from countries with market economies remained at the January 1, 1972 rate of 5% ad valorem for unwrought rhenium metal, and 9% ad valorem for wrought rhenium metal. The duty on wrought and unwrought rhenium metal from countries with centrally controlled economies also remained unchanged at 45% and 25% ad valorem, respectively. The duty on imports of ammonium perrhenate from countries with market economies was 4% ad valorem, and that from countries with centrally controlled economies was 25% ad valorem. The duty on rhenium waste and scrap was suspended until June 30, 1975.

WORLD REVIEW

Canada.—The Island Copper Mine of Utah International, Inc. (UI), near Port Hardy, British Columbia, contains one of the richest concentrations of rhenium in the world. Shipments have steadily increased since inception of the operation in 1972, when shipments of molybdenite concentrate to U.S. and Western European refineries totaled 400 tons containing about 1,200 pounds of rhenium. In 1973, shipments totaled about 1,200 tons containing approximately 3,200 pounds of rhenium; 1974 shipments totaled about 1,500 tons containing approximately 3,700 pounds of rhenium. Molybdenite purchasers have either paid for the contained rhenium or recovered the rhenium on a toll basis and returned it to UI.

Chile.—The proposed rhenium recovery plant of Cía. de Acero del Pacífico S.A. (CAP) at Concepcíon is still in the initial proposal stage. However, there has been no work at the site for over a year, and due to lack of financing, the future of this facility is questionable.

The privately owned firm, Carburo y Metalurgia S.A. (Carbomet), continued to recover rhenium in the form of ammonium perrhenate for export, at its plant in Santiago. Capacity is about 2,700 pounds per year. Currently, Chile's total rhenium recovery capacity is about 3,600 pounds per year.

The rhenium content of Chilean MoS_2 in porphyry copper deposits runs from about 230 parts per million (ppm) at Chuquicamata to 570 ppm at El Salvador with varying degrees in between at other operations.[3]

Peru.—Rhenium reserves were estimated in a preliminary report at about 352 tons representing 19% of estimated world reserves of approximately 1,900 tons.[4] There is currently no rhenium production in Peru, yet about three-quarters of the Peruvian MoS_2 exported from the Toquepala copper operation to West Germany and Sweden is processed for the contained rhenium. The rhenium content of the MoS_2 averages over 300 ppm.

TECHNOLOGY

The Bureau of Mines was granted a patent on its process for recovering rhenium from solution. The process consists of (1) contacting the solution with an adsorbent consisting essentially of activated carbon to selectively absorb the rhenium and (2) eluting the adsorbed rhenium from the activated carbon by means of an eluant comprised of a water-soluble alcohol or a mixture of a water-soluble alcohol and water. Rhenium recovery in excess of 96% was achieved by the procedure.[5]

The Bureau continued its studies to develop improved, low-cost leaching processes for the economical recovery of copper and byproducts, such as rhenium, from ores, concentrates, and mine wastes.

Atomic absorption of rhenium using a neon analysis line was studied. It was determined that the rhenium detection limit is no more than an order of magnitude greater, and in some cases less, than those determined with rhenium hollow cathode lamps. Therefore, it was concluded that neon-filled hollow cathode lamps can be used for the practical atomic absorption analysis of rhenium.[6]

A cobalt-44 atomic percent rhenium amorphous alloy was formed by electrodeposition from a bath first developed in 1952. The fabrication of this new amorphous metal was significant in view of the current interest in these materials and the fact that few such alloys have been electrodeposited.[7]

The oxidation of columbium-rhenium single crystals in dry oxygen between 500°C and 1,000°C was studied. Rhenium additions reduced the oxidation rate of pure columbium but only at temperatures below 650°C; greater additions yielded a more marked reduction in the oxidation rate. In the oxidation of pure columbium, suboxide platelets, anisotropic scale-failures, and a transition to breakaway kinetics are only observed at temperatures below about 625°C. Rhenium additions effectively reduced the time to breakaway by at least two orders of magnitude. Rhenium additions also appear to reduce the dynamic stability of suboxide platelets and to produce unusual anisotropic scale-failures on oxidized single crystals. Rhenium seems to dissolve in Cb_2O_5 to produce a more "plastic" and adherent scale. At higher temperatures, the oxidation rates of the alloys approach that for pure columbium as rhenium is probably removed by the volatilization of Re_2O_7.[8]

Separation of rhenium (VII) from chromium, cobalt, copper, iridium, iron, manganese, molybdenum, nickel, ruthenium, tungsten, uranium, and vanadium was achieved by solvent extraction with 4-methyl-2 pentanol (methylisobutylcarbinol) either from sulfuric or hydrochloric acid media. The results are accurate to within ±0.5%, and the total single extraction operation requires less than 30 minutes.[9]

A paper dealing with the properties, occurrence, and extensively with the chemistry of rhenium compounds was published during the year. It is particularly interesting for its bibliography of 548 items.[10]

The Bureau was granted a patent on the extraction of molybdenum and rhenium values from molybdenite. The process consists of electrolyzing a slurry of finely divided ore and sodium chloride at a temperature of preferably 30° to 50°C and a pH of from 5.5 to 6.5 in a bipolar flow-through cell, whereby the values are electrooxidized. A solution containing the values is separated from the gangue solids and subjected to conventional processing methods.[11]

Kennecott Copper Corp. received a patent on recovery of rhenium from industrial solutions. A solution obtained by scrubbing molybdenite roaster flue gas or a raffinate from ion exchange or solvent extraction is reacted with hydrogen sulfide or silicon sulfide in the presence of either iron, nickel, or zinc powder at a pH of from 0.5 to 3.5 to precipitate insoluble rhenium values. Subsequently the reaction mixture is filtered to recover the rhenium values.[12]

A patent was granted to PPG Industries, Inc., on the extraction of molybdenum and rhenium from molybdenite. Finely divided ore is contacted with an ammonium, a stable alkali metal, or alkaline earth metal, persulfate solution at a temperature of preferably 25° to 40°C, whereby a substantial proportion of the molybdenum is solubilized and dissolved along with copper and iron, whereas most of the rhenium remains in the undissolved residue. The leach solution is then separated and processed for molybdenum, and the solids, for rhenium.[13]

A recycle process was patented for the recovery of rhenium by solvent extraction from molybdate solutions. The organic extractant solution, stripped of most of its rhenium content, was blended with sufficient organic active extractant to attain essentially the same rhenium extraction efficiency that is achieved with a comparable extractant solution prior to initial contact with molybdate-rhenium solutions. Such recycling results in eventual recovery of a very high percentage of rhenium.[14]

Salt

By Charles L. Klingman [1]

In 1974 salt production returned to its previous growth rate of about 5% per year for the first time since 1970. Total production was 46,423,000 tons, compared with 44,298,000 tons in 1973. Statistics for salt sold or used showed rock salt leading the increase with a 20% gain over the quantity of rock salt sold or used in 1973. There were also small gains in vacuum-pan and open-pan salt, but solar salt and salt in brine remained relatively stable.

All salt prices advanced in 1974. The price of vacuum-pan salt averaged 18% higher than in 1973, probably because of the sharply rising cost of fuel needed for evaporation. By contrast, solar salt and salt in brine, which used very little fuel, advanced only 3% in average price. Rock salt prices increased about 15% over the 1973 prices.

Total salt sold or used by producers increased 2.8 million tons during the year, which included a 1.7-million-ton increase in highway use.

Legislation and Government Programs.—The Environmental Protection Agency (EPA) had significant influence on the production of several compounds made from salt through its regulation of the effluents from the plants. The sharp decline in synthetic (Solvay) soda ash output over the past 8 years has been due primarily to EPA restrictions on the amounts of allowable salt and calcium chloride permitted in streams, rivers, and lakes which receive the plant wastes. There have been five shutdowns of Solvay soda ash plants since 1966. Salt consumption for soda ash manufacture has dropped an average of 350,000 tons per year each year since 1966.

In 1974, announcements were made as to the possible carcinogenicity of vinyl chloride and the depletion of the ozone layer of the stratosphere by chlorofluorocarbons. Production of vinyl chloride and chlorofluorocarbons, both of which contain chlorine, was significantly reduced, and this in turn reduced the demand for salt to manufacture the chlorine.

In September 1974, the United Salt Corp. of Houston, Tex., was given approval by the U.S. Food and Drug Administration (FDA) to sell salt obtained as a byproduct of chlorine-caustic electrolysis for use as food-grade salt. The FDA action was challenged in the courts on the contention that such salt might contain harmful asbestos fibers. In April 1975, the FDA reversed its previous ruling and decertified this byproduct salt for use in food.[2] None of the byproduct salt was known to have been marketed.

The salt industry has traditionally enjoyed a 10% depletion allowance on its production, but this tax-reducing allowance was under study by Congress in 1974 and may be either reduced or eliminated.[3]

r Revised.

[1] Excluding Puerto Rico. 32,000 short tons (1970), 28,500 short tons (1971), 29,000 short tons (1972, 1973, and 1974).

DOMESTIC PRODUCTION

Total salt sold or used in 1974 was about 6% higher than that of 1973; the largest gain occurred in rock salt, which had a 20% increase. There were also slight increases in vacuum-pan and open-pan evaporated salt sold or used.

The five leading States in the amount of salt sold or used are as follows, in descending order:

State	Percentage of total
Louisiana	29
Texas	24
New York	14
Ohio	11
Michigan	10
Total	88

In 1974 there were 95 salt-producing plants operated by 52 companies in 15 States and Puerto Rico. Twelve of these companies produced 88% of the total salt. The percentage of salt sold or used in 1974 by type is as follows:

	Percent
Salt in brine	55
Mined rock salt	32
Vacuum-pan salt	8
Solar-evaporated salt	4
Grainer or open-pan salt	1

An estimated 9,200 workers were employed by all of the salt companies, about 28% in mining and 72% in processing salt.

The International Salt Co.'s crystallizing plant in Cleveland, Ohio, was closed in February 1974 because the novel process was not competitive with existing vacuum-pan operations. The salt mine at this location continued to operate normally.

[1] Data does not add to total shown because of independent rounding.

STOCKS

The 1974 Bureau of Mines survey obtained information for the first time on salt stocks on hand at yearend. Although the coverage was incomplete, it indicated that the total salt held by all producers was about 4.7 million tons, or 10% of the annual production. Over half of this tonnage was in the form of rock salt, and most of the remainder was solar salt. Solar salt had the highest percentage of its production in stocks. Rock salt stocks were about 17% of the annual production, and evaporated salt had only 3.5% of its annual production in stocks. The brine industry had very little inventory of salt on hand at yearend.

CONSUMPTION AND USES

Consumption of salt on highways showed a 28% gain over the 1973 tonnage because of more severe weather conditions. Use of salt for manufacturing chlorine increased nearly a half million tons. There were significant reductions in salt used by feed mixers and for soda ash manufacture, and there were smaller reductions in paper and pulp and in grocery store use.

In 1974 the United States imported 7% of its apparent salt consumption and exported about 1% of its production. Net imports (imports minus exports) were 2.8 million tons, 9% greater than net imports for 1973.

Production of chlorine and caustic soda continued to be the leading salt user in 1974 at 49% of the total, but the rate of usage for chlorine dropped considerably toward yearend. The amount of salt going to synthetic soda ash dropped in 1974 to 4.56 million tons, a 4.5% reduction from usage in 1973.

W Withheld to avoid disclosing company confidential data; included with "Other."

[1] Less than ½ unit.

[2] Includes shipments to overseas areas administered by the United States, Puerto Rico, exports, some shipments to unspecified destinations, and States indicated by symbol W.

[3] Data may not add to totals shown because of independent rounding.

[4] Differs from totals in tables 2, 4, and 5 because of changes in inventory.

[5] Differs from totals in tables 1, 11, 12, and 13 because of incomplete data on the distribution of imported salt.

PRICES

Salt prices quoted at yearend 1974 by Chemical Marketing Reporter, unchanged from 1973, follow:[4]

	Per 100 pounds
Salt, evaporated, common, 100-pound bags, carlots or truck-lots, works	$1.48
Salt, chemical-grade, same basis	1.54
Salt, rock, medium coarse, same basis	.97
Salt, rock, extra coarse, same basis	1.02

The average value of different classes of salt in bulk, f.o.b. works, as reported by salt producers in the Bureau of Mines annual survey follow:

	Per ton	
	1973	1974
Evaporated:		
Open pans or grainers	$31.52	$34.18
Vacuum pans	29.32	34.56
Solar	8.99	9.30
Pressed blocks, all sources	32.62	36.77
Rock salt, bulk	6.19	7.14
Salt in brine	3.57	3.69

Fuel costs escalated sharply in 1974 and were passed on in the value of the finished products, especially in vacuum-pan evaporated salt.

The weighted average price increase for all salt was 11%; the greatest increase was in vacuum-pan salt with a gain of 18%; and the lowest increase occurred in solar salt and brine at 3.4%.

FOREIGN TRADE

In 1974 the United States imported 6.8% of its apparent consumption and exported 1.1% of its production. Importation of salt from the Bahamas was primarily an accommodation to the economy of these islands. Shipments of about 1 million tons of salt up the Pacific coast from Mexico to California, Oregon, and Washington were used primarily in the pulp and paper industry of the Northwest.

The salt trade across the Canadian-United States border occurred in both directions where shipping distances could be kept shorter than that required for domestic salt. The United States imported 1,238,000 tons from Canada, but exported 464,000 tons, a net importation of 774,000 tons. The nominal tariff imposed on imported salt apparently had little effect on the movement of salt into the United States.

Tables 11, 12, 13, which report salt imports to the United States, were prepared from data supplied by the U.S. Department of Commerce. Table 14, however, was based on the Bureau of Mines salt survey and apparently covers only 87% of the total imports.

WORLD REVIEW

World salt production in 1974 was estimated at 172 million tons. Distribution of the salt production in 1974 by continent follows:

	Million tons	Percent
Europe	67.2	39
North America	59.0	34
Asia	33.4	20
Oceania	5.4	3
South America	5.3	3
Africa	2.1	1

The 12 top-ranking salt-producing nations, which accounted for 81% of the world's salt, are listed below in order of percent of world salt output:

	Percent
United States	27
People's Republic of China	11
U.S.S.R	8
Germany, West	7
United Kingdom	5
India	4
France	4
Italy	3
Canada	3
Australia	3
Mexico	3
Poland	2

Australia.—Solar salt production in Western Australia became a major industry with production of about 5.3 million tons per year, and this rate was expected to double within a few years. Capital expenditures for salt production were estimated at $79 million. The companies operating in Australia were Shark Bay Gypsum Co., Dampier Salt, Ltd., Leslie Salt, Pty., Ltd., Texada Mines, Ltd., and Lefroy Salt, Pty., Ltd. Most of the salt produced was exported to Japan.[5]

Canada.—Domtar Chemicals Ltd. was expanding its salt facilities at Unity, Saskatchewan, by 38% to 200,000 tons per year. Expenditure for this addition was estimated at $1.5 million.[6]

China, People's Republic of.—The People's Republic of China (PRC) continued to be the world's second-ranking producer of salt. Mechanization and bulk handling techniques were responsible for gains of as much as 25% in 1974 output. Most of the PRC's salt came from solar evaporation of seawater, and many valuable byproducts besides salt were extracted from this raw material. Some of the salt fields were inland, such as the Chilantei field in Ningsia Hui Autonomous Region, but most of them lay along the coast. The largest of these was the Tangku salt field on Pohai Bay near the city of Tientsin. Rock salt was mined in Yunnan, Kiangsi, and Hunan Provinces.

Denmark.—A major salt producer in Denmark was Dansk Salt I/S, located near the town of Hvornum in eastern Jutland. The salt supply was a salt dome about 1.9 miles in diameter and 2.5 miles in depth located about 2,000 feet below the surface. Solution mining was employed to remove the salt, and the brine was evaporated in vacuum pans. Production capacity was estimated at 386,000 short tons per year.

Salt production in Denmark in 1973 was reported to be 406,000 short tons; 184,000 short tons were exported, primarily to Sweden and Norway. These exports were offset by the importation of 189,000 tons of salt primarily from West Germany, Italy, the U.S.S.R., and Poland.[7]

Mexico.—The world's largest solar salt producer, Exportadora de Sal of Guerrero Negro, Baja California, has previously supplied Japan under contract 2.8 million tons of salt per year at $3.56 per ton. In June 1974, the contract was increased to ship 3.3 to 3.7 million tons of salt per year at a 40% increase in price to $4.98 per ton. A project is under construction which will increase production capacity by 38% to 6.5 million tons per year.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] Salt is produced in many other countries, but quantities are relatively insignificant or reliable data are not available.

[2] Less than ½ unit.

[3] Includes an average annual production in the Canary Islands of about 13,000 short tons of marine salt.

[4] Year beginning March 21 of that stated.

[5] Excludes Victoria.

TECHNOLOGY

A survey of the energy requirements for various types of salt production was conducted in 1974. Average energy usages for the different classes of salt follow:

	Kilowatt-hours per ton	Thousand Btu per ton
Salt in brine	6.0	20.5
Solar-evaporated salt	23.5	80.1
Mined rock salt	29.5	101
Vacuum-pan salt	1,230	4,190

U.S. dependence on foreign oil has frequently led to the suggestion that about a year's supply of petroleum be stored for future use in underground cavities created by solution mining of salt. The storage volume required would be about 3.2 billion barrels, or 18 billion cubic feet. The volume created by all the solution mining of salt in 1974 would accommodate less than 8 days of U.S. petroleum consumption. About 47 years of solution mining at this rate would be required to create sufficient storage volume for 1 year's petroleum supply. This figure is a minimum and would apply only if there were no cavern failures and if all of the underground volume were made available for petroleum storage. Neither condition is a practical probability. There are no known salt cavities which are not now being utilized for other purposes.

At Huntorf, West Germany, an abandoned salt cavity is to be used to store compressed air which will be pumped into the cavity during off-hours and withdrawn to generate electricity during peak demands. The cavern has a volume of about 10 million cubic feet and is 2,000 to 2,600 feet below the surface. Air pressure up to 1,000 pounds per square inch will be used. The powerplant is designed to deliver 290 megawatts of power.[8]

Preliminary steps toward building a 100-million-gallon-per-day desalination plant to be fed by Colorado River waters were taken by the Office of Saline Water, near Yuma, Ariz.[9]

A novel use for salt was under development by the firm of Pope, Evans, and Robbins in Alexandria, Va. About 1 part of salt and 10 parts of limestone were injected into the combustion chamber of a small boiler to minimize sulfur contamination in the stack gases. Limestone was the active reagent to convert the gaseous sulfur compounds to filterable solids, and the salt apparently acted only as a catalyst in the reaction. The presence of salt, however, improved the effectiveness of sulfur removal. The results of this experimental work will be applied to a full-size, 30-megawatt powerplant in Rivesville, W. Va., which is scheduled for startup about April 1976. If successful, this process could develop a sizable new market for rock salt.

Sand and Gravel

By Walter Pajalich [1]

In 1974, sand and gravel production, including industrial sand and gravel, decreased about 1% to 979 million tons, valued at $1.5 billion. The value increased about 7% over that of 1973.

About 97% of the sand and gravel produced was used as construction aggregate and about 3% was used as industrial sand and gravel. Of the total construction aggregate, about 96% was produced by commercial operations and 4% by government-operated pits with their own crews and equipment for use on publicly funded projects. Of the total construction aggregate, about 75% was used commercially and about 25% was used for publicly funded projects.

Alaska, with reported sales of 118 million tons of sand and gravel, became the leading State in the Nation. Most of this was unprocessed sand and gravel sold by the Bureau of Land Management from Federal lands for use in the construction of the oil pipeline. Accurate consumption figures on the pipeline will be available in 1975. When the increase of 102 million tons, above the usual sand and gravel production in Alaska, are excluded from the National statistics, sand and gravel production decreased about 11%.

---

[1] Puerto Rico excluded from all sand and gravel statistics.

[2] Data not directly comparable with those of previous years because of changes in industry coverage (1973, 1974) and canvass form (1974).

[3] Unit value of sand or gravel may be lower than construction aggregate (1974) shown in tables 2 and 3.

[4] Data may not add to totals shown because of independent rounding.

New Data Collection System.—The 1974 sand and gravel canvass form was modified. Every location where sand and gravel is mined, on land or water, was classed as an "operation" and a canvass form recording production and other data was requested annually. A company with numerous operations prepared a canvass form for each operation. In most cases a processing plant was part of the operation. At some operations there was no processing plant and the material was sold or used as mined.

In former years the number of sand and gravel mines in the United States was based on a processing plant count. Because some operations have more than one processing plant at one location and others have none, the mine count is now based on "operations" as defined above.

Production of sand and gravel and its use as a construction aggregate in 10 different use categories was collected. As "Concrete Aggregate" the use pattern has been divided into "Nonresidential and residential construction," "Highway and bridge construction," "Concrete products, such as blocks, pipe, bricks, etc.," and "Other uses such as dams, waterworks, airports, etc." Other processed aggregate uses were "Bituminous paving" and "Roadbase and subbase," "Fill," and "Other." As unprocessed aggregate the use pattern has been divided into "Fill" and "Roadbase and subbase."

All of the above uses of construction aggregate were classified into two divisions, aggregate material used for "commercial projects" and "publicly funded projects." Aggregate used for construction projects financed by county, State, or Federal government funds was classified as used on "publicly funded projects." Some counties, States, and Federal agencies own and operate, with their own crews and equipment, sand and gravel operations. These noncommercial operations were also canvassed, data on them were collected and included in the "publicly funded projects" classification. About 4% of the Nation's sand and gravel came from these operations.

Production data were collected as sand and gravel and the use pattern data were collected as construction aggregate. Unit value per ton of sand or gravel, in most were made comparable with the 1974 format wherever possible.

For statistical continuity, the 1973 data were made comparable with 1974 format wherever possible.

Data in tables 11 to 15 will be collected on a 3-year rotational supplemental form. The same data will appear again in 1977 and in 1980. Other basic data about the industry will be collected in 1975 and 1976, and repeated in subsequent 3-year periods.

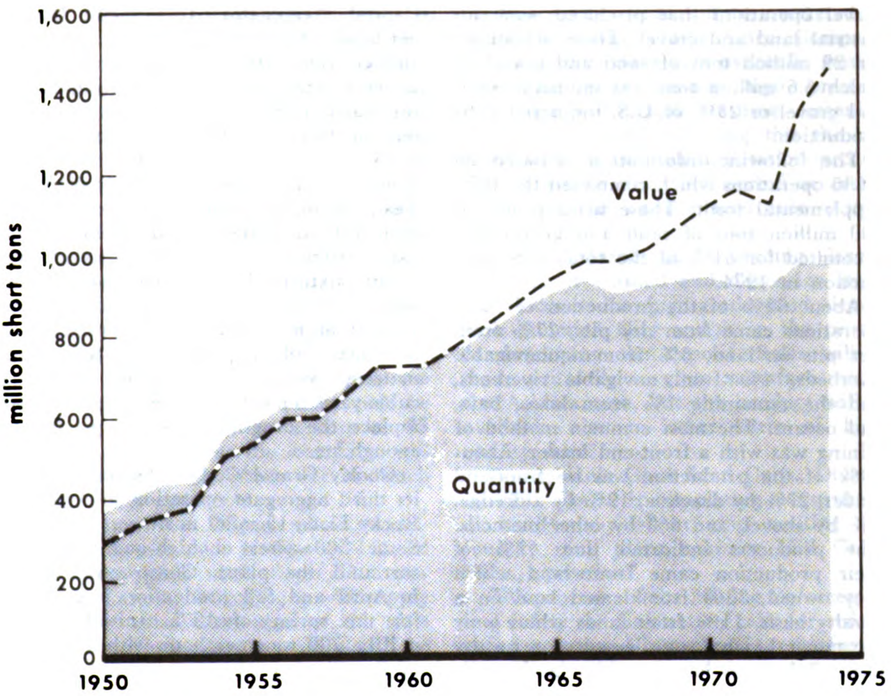

Figure 1.—Production and value of sand and gravel in the United States.

DOMESTIC PRODUCTION

Alaska, with reported sale of 118 million tons of sand and gravel ranked first in the Nation. California was second with a production of 105 million tons. Michigan ranked third. Other States producing substantial quantities of sand and gravel, in descending order of production, were Illinois, Texas, Ohio, Minnesota, and New York. Combined, the eight leading States accounted for 477 million tons, about 49% of the total U.S. output. The value of sand and gravel in these eight States was $619 million, 43% of the Nation's total.

The number of construction and industrial sand and gravel operations increased from 5,681 in 1973 to 6,967 in 1974. This was due in part to increased coverage of the industry. These operations were owned by 4,844 companies.

Of the 6,967 sand and gravel operations, 5,718 had processing plants associated with their land or dredging operations, 1,249 had no processing plant and the material was sold as mined. Some of the 5,718 operations have more than one plant on location for processing mined material from a single pit.

There were 5,637 construction sand and gravel operations with a production under 200,000 tons per year. These operations accounted for 33% of the total U.S. production. There were 780 operations with production between 200,000 and 500,000 tons, and they accounted for 26% of the production. The remaining 331 operations, with production over 500,000 tons, accounted for 41% of production.

There were 118 operations in the United States that produced only industrial sand and gravel and accounted for 22 million tons or 77% of the U.S. industrial sand production. All of these had a processing plant associated with the operation. Of these there were 107 operations with a production under 500,000 tons per year.

There were 101 construction sand and gravel operations that produced some industrial sand and gravel. These accounted for 29 million tons of sand and gravel of which 6.6 million tons was industrial sand and gravel or 23% of U.S. industrial sand production.

The following information is based on 5,636 operations which completed the 1974 supplemental form. These firms produced 790 million tons of sand and gravel and accounted for 81% of the total U.S. production in 1974.

About 62% of the production of these operations came from dry pits, 27% from wet pits on land, 6% from nonnavigable riverbeds, 4% from navigable riverbeds, and the remaining 1% from lakes, bays, and oceans. The most common method of mining was with a front-end loader. About 39% of the production was by front-end loader, 27% by dragline, 19% by a dredge, 9% by shovel, and 6% by other methods. The producers indicated that 47% of their production came from land which they owned, 33% from leased land on a royalty basis, 11% from lands where only the mineral rights were leased on a royalty basis, 7% from leased public lands on a royalty basis, and 2% was mined from lands where they own only the mineral rights.

The total estimated capital investment at these operations was about $2 billion. Capital investment was based on the estimated 1974 yearend market value of all physical fixed assets including mining equipment, processing plant, buildings at mine site, and all trucks, barges, or other transportation equipment associated with production. Excluded are cost of land, mineral rights, and inventories. The estimated sand and gravel reserves at 3,145 operations which responded to this question was 8.4 billion tons.

Factors that have added to the consumer cost of sand and gravel included increased labor costs, growing land values, cost of land rehabilitation, cost of fuel, and longer haulage distances.

The industry continued to make progress in the use of larger operating units, more efficient portable and semiportable plants, versatility of plant capacity, and greater awareness of pollution control and land rehabilitation.

Mechanization of material handling has virtually eliminated the need for haul trucks and front-end loaders within the Capital Aggregates, Inc., new 715-ton-per-hour sand and gravel plant. Field and conventional belt conveyors, traveling stackers, and gravity withdrawal, handle the material from the pit, through processing and to loadout hoppers. Capital Aggregates, is a subsidiary of H.B. Zachry, Inc. The new plant, located southeast of Austin, Tex., occupies some 459 acres of land divided by the Colorado River. The deposit varies from 65% sand, 35% gravel, to a 50-50 mixture. The average depth of the deposit is 36 feet. It is covered by about 10 feet of fine sand which is used in the hot mix asphalt plant or is sold as fill material. Mining is being done by a 3-½-cubic-yard bucket dragline. A dredge will replace the dragline once the pit is large enough.[2]

Cooley Gravel Co. of Denver will open its third aggregate operation in 3 years at Rocky Flats, 15 miles northwest of Denver. Some 500 acres of high-quality reserves surround the plant. Construction started in April and full production is scheduled for the spring of 1975. Initial capacity will be 700 tons per hour with a potential of 1 million tons per year.[3]

West Coast Silica, of Overton, Nev., has been purchased by Johns-Manville Corp. and will operate as part of the latter's mining division. The silica sand is used in asbestos cement pipe, for irrigation, and water and sewage transmission.[4]

Spezio Construction Co. purchased the Pittsford Gravel Corp. at Mendon, south of Rochester, N.Y., in 1961, and mined the deposit profitably until 1968. The company than decided to make the mined out pit a landfill for demolition and excavation debris to build the 580 acres up to ground level for a 3,000-unit housing development. Careful engineering, planning and execution, and a great deal of public relations work were needed to overcome obstacles to the project. With the landfill now almost completed, work will start on the housing development with many benefits for the town of Mendon.[5]

[4] Rock Products. Rock Newscope. V. 77. No. 3, March 1974, p. 17.

[5] Pit & Quarry. Public Antagonism Converted to Staunch Program Converting Waste Site to Valuable Property. V. 66, No. 8, February 1974, pp. 84–85, 89.

Yuba Goldfields, Inc., of California has formed the Yuba Aggregate Division as the firm's marketing branch for sand and gravel throughout the State. The company is planning to develop a major cement and concrete manufacturing-oriented industrial complex at Yuba's 10,000 acre site at Hammonton.[6]

HC&D, Ltd., announced plans to begin producing artificial sand within 18 months in Hawaii. "Man-sand," short for manmade sand or manufactured sand, will be made from pulverized lava rock dug from the firm's Kapaa quarry on Windward Oahu. The new sand is reported to be stronger than coral beach sand and is competitive in price. Under present projections, the plant situated next to the quarry, will be completed in mid-1975 at a cost of $5 million. At that time, the company will be able to completely phase out its beach sand dredging operation.

Construction has begun on a several-hundred-acre site near Hoffman, N.C., of a new silica glass sand plant. The new company, Carolina Silica, Inc., will supply high-quality silica glass sand to the glass industry in North Carolina. This will be the only plant of its kind in the State. The plant, located approximately 12 miles south of Southern Pines on U.S. Highway No. 1, will also produce filtration and blasting sand, which will be marketed by Southern Products and Silica Company. Mining will be done by a hydraulic method employing water under high pressure. Processing will include washing, screening, and classification. Following this the material will go through a flotation process, then it will be dried and sorted according to particle size and placed into storage silos.[7]

Georgia Marble Co., a leading Georgia producer of crushed and dimension stone, has discovered a high-grade sand deposit near Junction City and is in the process of developing the deposit. Sales will be made primarily to glass manufacturers in the Atlanta area, but the product will be available also to other users of high-quality sand.

Pennsylvania Glass Sand Corp., Division of ITT, Corp., is completing construction of a 134-ton-per-hour glass melting and foundry sand plant near its Mill Creek, Okla., operation.[8]

The program of the Mining Enforcement and Safety Administration calls for stricter enforcement and inspections in the future. By 1975, they expect to inspect every aggregate operation in the country.

CONSUMPTION AND USES

In 1974, U.S. consumption of sand and gravel amounted to 979 million tons valued at $1.5 billion. The construction industry, the prime user of sand and gravel, consumed 97% of the tonnage, representing 90% of the value of the sand and gravel output in 1974. Of the sand and gravel consumed by the construction industry as concrete aggregate, 24% went into nonresidential and residential construction, 8% into highways and bridge construction, 7% into concrete products, and 2% into other. Bituminous paving consumed 15%, roadbase and subbase 16%, fill 3%, and other consumption 2%. As unprocessed sand and gravel, 11% was used as fill and 12% as roadbase and subbase.

Industrial uses were expanded to include gravel which was used for metallurgical purposes.

PRICES

Representative carlot prices of sand in 14 cities at the end of 1973 ranged from $1.35 per ton in Detroit to $5.50 per ton in Chicago, according to the Engineering News-Record.[9] The average of the sand prices reported was $3.05 per ton compared with $3.55 per ton in 1973. Prices for either ¾- or 1½-inch gravel ranged from $0.75 per ton in Birmingham to $5.45 per ton in Los Angeles. The average of the ¾-inch gravel prices reported for 14 cities was $3.55 per ton compared with $3.66 per ton in 1973. For 1½-inch gravel, the average for 14 cities was $3.52 per ton compared with $3.92 per ton in 1973.

[7] Pit & Quarry. Carolina Silica Building Glass Sand Operation. V. 67, No. 2, August 1974, p. 19.

[8] The Glass Industry. Newsletter. V. 55, No. 7, July 1974, p. 6.

[9] Engineering News-Record. V. 193, No. 24, Dec. 5, 1974, pp. 28–29.

Based on the Bureau of Mines canvass, the average value of processed sand and gravel sold or used by producers, f.o.b. plant, was $1.64 per ton; unprocessed sand and gravel was $0.54; industrial sand and gravel was $4.77 per ton. Overall average value of sand and gravel was $1.48; the comparable value in 1973 was $1.38.

FOREIGN TRADE

The U.S. exports gravel, construction sand and gravel, and industrial sand. In 1974, gravel exports totaled 472,896 tons, valued at $667,942, construction sand and gravel totaled 658,801 tons, valued at $1,131,845, industrial sand totaled 1,123,954 tons, valued at $9,864,134. Canada received 98% of the gravel and Mexico 1%, and the remainder was shipped to 20 different countries. Canada received 88% of the construction sand and gravel and the Bahamas 11%; the remainder was shipped to 26 different countries. Canada received 68% of the industrial sand and Mexico 28%, and the remainder was shipped to 58 other countries.

Most of the crude sand and gravel imported in 1974 was from Canada. Almost all of the imported glass sand was from Australia.

WORLD REVIEW

France.—In 1973 France produced 207 million tons of gravel. The projected production rate of the industry is expected to grow at 9.3% per year for the next 5 to 6 years. Most of the sand and gravel industry is dispersed, with a few major companies and many family businesses. The major sources of sand and gravel are the Seine, Rhône, Loire, and Rhine Valleys. Imported sand and gravel comes from the United Kingdom. British sea-dredging companies land marine gravel at channel ports, particularly at Dunkirk.

The Groupe Garon, in Lyons, is the second largest sand and gravel producer in France with an annual output of 12 million tons. The firm has operations on land and also dredges in the Rhône and Saone Rivers. Another large company, Compania des Sablières de la Seine at Bernières, some 13 miles southeast of Rouen, is mining a deposit alongside the river. Using dry-mining methods for the material above the water table and a dragline below the water table, the company produces about 7,500 tons per day. About 80% of the sand and gravel from this deposit is barged into Paris and the remaining amount is trucked there.[10]

Germany, West.—To meet the shortage of natural sand in West Germany's upper Bavarian region, a crushing plant was designed and erected by Freid R. Krupp. GmbH, near Rosenheim on the bank of the Inn River. The crushing plant reduced 32 to 100 millimeter rounded gravel to 0 to 4 millimeter concrete sand. The capacity of the plant is 50 tons per hour.[11]

Panama.—The new 200-ton-per-hour plant of Cantera Le Esmeralda near Ojo de Agua, is capable of simultaneously producing three different rock products plus sand. It can load and/or stockpile three different products at the same time. The operation can sell seven different products, either washed or dried. Most of the processing is controlled by a single operator at a station above the jaw crusher.[12]

Sweden.—A new Swedish law requires all machinery used for aggregate production to be totally enclosed, preferably in rubber. The law, while primarily designed to prevent dust, is also intended to cut down noise, and applies regardless of the plant location. The first aggregate plant to be built since the law was adopted was Armerad Betong at Sodra Sandby in south Sweden by A. B. Mataki, one of the largest road contractors in Sweden. The plant is located in a forest area away from any populated community. Dust sealing is achieved with rubber cloth and fabric. The dust exhaust from the crushing and screening units is trapped in dust collectors. Effectiveness of the airtight seals made it possible to reduce the size of fans and filters, in comparison to the use of conventional open hoods. The noise level was cut by the dampening effect of the rubber by 15 to 20 decibels.[13]

United Kingdom.—During the past 10 years the trend in the United Kingdom has been toward establishing fewer but larger sand and gravel companies. One of the major reasons behind this trend seems to be the increasing installation and upkeep costs of a new plant. A larger part of this stems from stricter environmental control regulations. It is not uncommon for efficient dust control and ancillary environmental protection equipment to cost at least as much as the processing plant. Also, the cost of the new plant often increases with size. Although the internal structure of the companies involved in sand and gravel industry has changed, the processing equipment used and services offered are still the same.

The Stevens and Verney Committees, appointed by the Government in 1972, continued their investigation of problems relating to the aggregate industry. The Stevens Committee is reviewing legislation concerned with the planning control of mineral extraction and the Verney Committee is looking into questions relating to the supply of aggregates. A preliminary report has been issued by the Verney Committee.

Committees of the British Standards Institutions have changed and revised standards for rolled asphalt which eliminated many arbitrary restrictions. These restrictions formerly excluded many gravels from use in roads. New standards for concrete aggregates and building sand have been published. These standards will permit and require the testing of aggregates in metric terms. This will complete the changeover to the metric system for the sand and gravel industry.

The British Sand and Gravel Association, Ltd., research team is classifying aggregates. They are primarily concerned with the mechanical properties of aggregates in an unbound state for use as roadbase. Their laboratories are testing aggregates for shear strengths. Pilot-scale trials are being linked to the results of laboratory studies to establish levels of shear strength required for satisfactory subbase performance. Also, simple compaction tests are being developed for use in concrete and bituminous mixes.

Recent modifications of British Standards for bituminous roadbase materials will permit, in future design procedures, a wider range of aggregates than at present and the composition will be related to performance requirements.

The compositions of most bituminous-coated road materials were covered in British Standards and bituminous mixes of other compositions were included in the Department of Environment's Specification for Roads and Bridges. These standards contained some mixes which were seldom used and materials of very similar composition were found in the various standards. Because of these complexities and changes in use and road-loading conditions, one set of British Standards covering all types of bituminous-coated road materials have been adopted.[14]

A single screw sand and gravel suction dredge, built by Ailsa Shipbuilding Co., Ltd., has been delivered to British Dredging, Ltd. The 4,425-ton vessel is designed to pump 2,200 tons of dredged material per hour at depths of 75 feet. However, the vessel can operate at depths of 148 feet when necessary. The dredged material is processed and stored in the hold. On every voyage the dredge can produce 3,556 tons of drained sand and gravel.[15]

Britain's largest producer of aggregates has installed radar on their pit tugs used to push sand and gravel laden barges from the extracting area to the processing plant. Because of the company's policy on reclamation, islands have been left in the pit. The prime objective of the radar is to prevent the tugs from running aground. On a foggy day losses from running aground have been as high as 800 tons of production. Each barge carries about 150 tons. With radar, the tug operators can home in on a selected guide post and deliver their cargo safely to the plant.[16]

Yugoslavia.—Gammerler & Co. delivered a complete aggregate processing plant for a ready-mix concrete operation in the center of Belgrade. The plant was specially designed to fit a limited space on the right bank of the Danube. The sand and gravel is delivered in ships with a 70,000-cubic-feet carrying capacity. Unloading is done by floating unloaders. The unloaders are equipped with scoop wheels that can be lowered into the ships. On land the material is fed from the stockpile to the processing plant. The processing plant consists of six steel silos, five with a capacity of about 7,000 cubic feet and one with a capacity of 10,000 cubic feet, a jaw crusher for oversized material, two double-deck screens, a 6-inch centrifugal pump, and 8-inch hydrocyclones have been installed for sand recovery.[17]

TECHNOLOGY

Macomb County, Mich., highway officials are testing a thinner, less complicated pavement design expected to cut construction costs by 19% on 4 miles of roadway in metropolitan Detroit. The design has a 6-inch pozzolan base and a 7-inch nonreinforced concrete overlay. Conventional, comparable roadways have a 6-inch sand base, 4 inches of crushed stone, and 9 inches of concrete. The new design has no expansion joints; contraction joints are unpinned, and skewed and sawed at intervals of 15 to 18 feet. The pozzolan is a mixture of fly ash, lime, and sand aggregate. This slowly forms concrete when about 10% moisture is added. The concrete offers a savings in material costs. It is not known what effect the elimination of expansion joints will have on costs. Unpinned contraction cuts have been used since 1970, but expansion joints were eliminated this year for the first time. The overall effect of the test design on costs will not be known until next year. The design life of the pavement is 20 years.[18]

Use of gravel-bed filters for dust collection is increasing. There were 26 cement, lime, and refractory companies using high-purity quartz gravel to clean hot abrasive dusts. Gravel-bed filters at these operations have been found to be highly efficient, having low operation costs and needing little maintenance. They operate at temperatures up to 900° F. The gravel-bed itself is relatively unaffected by temperatures up to 2,000° F. Although the filters have been used mainly for dust separation in cement plants and in the lime industry, they find some application in other industries. The filter medium is made up of uniformly sized, almost round, rough-textured 99% silica gravel. The gravel ranges in size from one-half to 4 millimeters. The gravel-bed filter in the United States is built in accordance with an exclusive license agreement between Gesellschaft für Entstäubungsanlagen (GfE) of Münich, West Germany, and Rexnord, Inc., of Milwaukee, Wis.[19]

The Las Vegas Paving Co. is pilot testing an 80-ton-per-hour portable unit which will economically process and recycle asphalt rubble. The rubble would become a source of usable raw material in road-building. Patent applications have been filed covering the Recycle Machinery, Inc. (RMI) Roadrunner and its operation. The inventors claim the process is profitable with no dust or fume problems. They estimate that every thousand tons of broken asphalt pavement contains about 950 tons of crushed and graded specification aggregates and about 285 barrels of asphalt. A petroleum-based softening agent is an essential ingredient and a 1% to 2% addition of fresh asphalt is required. New aggregates are usually added to fill gradations. Overall savings are said to be up to 35%.[20]

A program designed to reduce dust has also resulted in savings in the grading and wetting of heavily traveled gravel surfaced plant roads. Cost savings have been running $223 per day at one location and the dust stirred up by trucks is virtually eliminated. Coherex, manufactured by Vitco Chemical Corp., Golden Bear Div., is a stable, concentrated cold water emulation of petroleum oils and resins. The material requires no heat and can be diluted with cold water, including seawater. The program involves continuous daily spraying for about 3 weeks. After this period the dirt and gravel surface becomes relatively smooth and dust free and requires only one daily spraying. Conrock Co. has found this program successful in controlling dust at their Irwindale plant in California.[21]

At the Bureau of Mines Tuscaloosa Metallurgy Research Laboratory, experiments are being conducted on the reclamation and beneficiation of foundry mold materials. The objective is to develop methods for reclaiming foundry sands by physical and pyrolytic beneficiation techniques. Also, research is being conducted on controlled expansion of foundry sands from low-grade olivine and on the suitability of other mineral products for foundry use. The Tuscaloosa Laboratory has been engaged in the development of structural materials utilizing reclaimed glass as the principal component.

A new handling method has been developed which allows aragonite, a pearly calcareous sand, to be used for beach restoration. The new method was developed by Marcona Ocean Industries of San Francisco. An 8-ton capsule assisted by two high-pressure water jets and equipped with a discharge pump and a specially designed eductor valve, can pump 400 tons of aragonite slurry ashore in an hour. Aragonite, the sand which forms most of the white beaches of the Bahamas Archipelago, has been mined from the ocean bottom and sold to the glass, cement, limestone, and carbonate beverages industries.[22]

[1] Data not directly comparable with those of previous years because of changes in canvass form.
[2] Unit value of construction aggregate may be higher than unit value of sand or gravel.
[3] Includes unprocessed sand and gravel (1973).
[4] Includes railroad ballast, miscellaneous and some unprocessed sand and gravel (1973).
[5] Data may not add to totals shown because of independent rounding.

Silicon

By E. Shekarchi [1]

The strong demand and tight market for silicon metal and ferrosilicon that existed in 1973 and the first 9 months of 1974 finally eased during the fourth quarter of 1974. Major producers were predicting not only the availability of silicon metal for 1975, but also a possible price reduction. Many silicon metal producers allocated their entire 1974 production to established customers with a price-in-effect-at-time-of-shipment clause. Market conditions, combined with rising production costs, especially for coal and coke, forced price increases several times during the first 9 months of 1974.

With plant expansion and/or modernization completed, domestic production of ferrosilicon and silicon metal showed an increase for the fourth quarter. Overseas production capacity for silicon metal and ferrosilicon was also increased as several new plants came into production during the year. By yearend, domestic stocks were 30.8% greater than at the close of 1973, reflecting increased world production and easing of the tight market.

Tyco Laboratories, Inc., after 2 years of research, developed techniques for producing a silicon ribbon, the basic material for the manufacture of solar cells.

DOMESTIC PRODUCTION

On a gross weight basis, net production of ferrosilicon and silicon metals and alloys increased only 1%, whereas shipments decreased 15.2% in 1974 compared with 1973 figures. Yearend stocks showed an increase of 30.8% in 1974 compared with those of 1973, reflecting decreasing demand by steelmakers for specialized raw materials, the growth of electric furnace capacity, and improved smelting technology.

The production of nominal 50% ferrosilicon decreased 7.8%, whereas ferrosilicon containing 56% to 70% silicon increased 8.6% during the year. The production of ferrosilicon with 71% to 80% silicon content increased 23.6%, but production of 81% to 95% ferrosilicon decreased to only 100 tons in 1974 from 3,785 tons in 1973. Production of silicon metal, consumed mostly by the chemical and aluminum industries, rose 5.2% compared with 1973 output. Ferrosilicon and silicon metals and alloys were produced at 24 plants by 14 companies, as shown in table 2.

Tyco Laboratories, Inc., Waltham, Mass., agreed to form a joint company with Mobil Oil Corp. to develop and market silicon ribbon, the basic material used in solar cells. After 2 years of research, Tyco Laboratories, a developer of diversified electronics and consumer products, was able to show that silicon ribbon could be produced economically. Under the agreement, Mobil Oil was to provide up to $30 million for the development and possible marketing of silicon ribbon. Mobil Oil Corp. was to own 80% of the newly formed company, and Tyco Laboratories, Inc., 20%.

Officials of Ohio Ferro-Alloys Corp. announced in July that it would build a 46-megawatt-ampere closed ferrosilicon furnace in Philo, Ohio. The company expected the plant to go into production by April 1975. Projected capacity of the plant was given as 40,000 tons of ferrosilicon annually.

In August, representatives of Dow Corning Corp. reported plans to build a silicon production plant in Carrollton, Ky. The plant was to produce semiconductor-grade silicon and was expected to cost $46 million. The expected completion date was given as July 1977.

---

[1] Physical scientist, Division of Ferrous Metals.

In January, the management of National Metallurgical Corp. announced plans to expand the production capacity of its silicon plant at Springfield, Oreg., from 4,500 to 13,000 tons annually. The expansion program was to cost about $5.5 million, including $1.5 million for pollution control equipment.

Foote Mineral Company's modernization program at Graham, W. Va., continued through 1974. Included in the modernization plan was the addition of a 20-megawatt furnace equipped with an air pollution control device. The plant was scheduled to resume full operation by mid-1975.

Officials of Union Carbide Corp. reported expenditures of $30 million to expand the production capacity of its plants at Alloy, W. Va., and Ashtabula, Ohio. The Alloy plant was to increase its silicon metal production capacity by 15,000 tons; the Ashtabula plant was to add 75,000 tons to its ferrosilicon production by yearend.

CONSUMPTION AND USES

Consumption of silvery pig iron, primarily by iron foundries, decreased 28.8% in 1974 compared with 1973 data. Ferrosilicon, used mostly for deoxidizing steel and producing silicon alloy steel and cast iron, also showed decreases in consumption. The greatest decrease, 32.8%, was in ferrosilicon with a silicon content of 56% to 70%; whereas decreases of 18.9% and 19.5% were reported for ferrosilicon with silicon contents of 25% to 55% and 81% to 95%, respectively. Consumption of ferrosilicon with a silicon content of 71% to 80% increased 22.8% over that consumed in 1973. In Europe and Japan, this grade of ferrosilicon also showed the highest consumption rate, probably reflecting a trend which was observed in the U.S. steelmaking industry in 1974.

Silicon metal consumption decreased 2.3% in 1974 compared with that of 1973. The decrease essentially was due to a reduction of aluminum output in the latter part of 1974. High-purity silicon consumption remained strong during the year. Producers and consumers of the polycrystalline and high-purity silicon were Texas Instruments, Incorporated, Motorola, Inc., Fairchild Camera & Instruments Corp., and Dow Corning Corp. All of these companies operated at full capacity during the year and anticipated new and expanded production capacities by 1975.

Silicone rubber compounds were found to be stable, durable, flexible, and unaffected by variant temperature. The main use for silicone resins was still electrical insulation, especially where elevated temperatures were expected, such as in roters, starters, and heavy-duty electrical motors. Silicone-based paints were used extensively in 1974.

[2] Includes magnesium-ferrosilicon and other silicon alloys.
[3] Included with "Miscellaneous and unspecified."
[4] Included with "Full Alloy Steel."

PRICES

After the Cost of Living Council decontrolled all ferroalloy prices in March 1974, ferrosilicon and silicon metal prices increased several times owing to higher costs of materials and energy. The f.o.b. price of 50% ferrosilicon increased from 18.5 cents per pound in 1973 to about 33 cents per pound contained silicon, bulk, carload lots, in 1974. Metallurgical-grade silicon, 98% minimum silicon, 0.35% maximum iron, increased from 28.4 cents in 1973 to 46.7 cents per pound contained silicon in 1974. Amorphous silicon in 50-pound paper bags, 200 mesh, 90% to 95% silicon, was increased to $28 per ton in 1974 from $27 in 1973.

The price increases for ferrosilicon and silicon metal in the first 9 months of 1974 were attributed to insufficient growth of production capacity during the previous 5 years, coupled with higher costs of energy and materials. However, during the final quarter of 1974, production from expanded old facilities and new installations increased supplies sufficiently to satisfy the demand. At yearend, producers were predicting possible price reductions in 1975.

FOREIGN TRADE

Exports of ferrosilicon and silicon metal decreased 58.9% in quantity and about 17.6% in value. Major recipients were Canada, 4,401 tons; Bolivia, 797 tons; Mexico, 416 tons; and The Republic of South Africa, 223 tons. Twenty countries received shipments of ferrosilicon and silicon metal ranging from 1 to 100 tons.

The trade imbalance in ferrosilicon evident in the United States in 1973 continued in 1974. Imports of ferrosilicon for consumption increased 41% in gross weight and 211% in value over those of 1973. Silicon metal imports for consumption decreased 31% in quantity but increased 40% in value as a result of inflated prices. Major increases in value were in both the not-over-99.7%-silicon-metal and the over-99.7%-silicon-metal categories. Total value of imports of ferrosilicon and silicon metal amounted to $83 million in 1974 compared with $33 million in 1973.

WORLD REVIEW

Canada.—In July 1974, officials of Suddeutsche Kalkstickstoff-Werks, A. Co. (SKW), of Trostberg, West Germany, announced plans to build a $40 million silicon metal and ferrosilicon plant in Becancour, Quebec, Canada. According to SKW, jointly owned by Hoechst Company and a German state firm, an annual production of 25,000 tons each of silicon metal and ferrosilicon was scheduled to begin in 1976.

India.—During 1974, production of ferrosilicon and silicon metal was about 28,000 tons, 20% below 1973 production. The decline was attributed to energy shortages and a decrease in the production of iron and steel and aluminum. Total ferrosilicon and silicon metal consumption by India's steel and aluminum industries was estimated at 25,000 tons in 1974, all of which was produced domestically. Exports of ferrosilicon in 1974 were about 3,000 tons—2,300 tons to the United States and the remainder to Singapore.

Japan.—Production of ferrosilicon and silicon metal in 1974 was 350,000 tons, 10% greater than that of 1973. To overcome possible ferrosilicon shortages in the future, producers were expanding present facilities or venturing into mergers domestically and overseas.

The management of Nippon Refining and Concentrating Co. was planning to add a 16,000-ton-per-year ferrosilicon plant at Kohma. The power for this plant was to be supplied from Nippon's Matsukawa powerplant at a reduced price. The completion date of the plant was given as early 1976.

The merger of Nippon Refining Co. with Tohuku Refining Co. was to be finalized in April of 1975. Tohuku operates a plant with a 22,000-ton-per-year capacity.

In October 1974, it was reported that Japan Metals and Chemicals Co. (JMC) had begun construction on the first of two new electric furnaces at Matsukawa. The furnace, using power from the JMC geothermal plant, was to have a capacity of 34,000 tons per year of ferrosilicon, and was expected to go onstream by 1976. Construction of the second furnace was to begin at that time.

A joint project between Nippon Denko Co., C. Itoh and the Philippine Laurel Co. was given confirmation regarding power availability for their proposed 23,000-ton ferrosilicon production facility in the Philippines. Completion of this project was expected sometime in 1977.

Portugal.—In September 1974, Companhia Portuguesa de Fornos Electricos (CPFE), was authorized by the Portuguese Government to proceed with its plan to install a second 25-megawatt-ampere ferrosilicon furnace at Canas. CPFE's first 25-megawatt-ampere furnace, under construction in 1974, was scheduled to produce up to 12,000 tons of silicon metal annually starting April 1975.

South Africa, Republic of.—African Oxygen Ltd., through its subsidiaryl Dawson and Dobson, teamed with two overseas companies—Aluminum Co. of Canada, Ltd. (ALCAN) and Foote Mineral Company of the United States—to form a silicon metal venture called Silicon Smelter (Pty.), Ltd. (SSPL), in 1973. The three partners shared equally in the venture. Construction of the new smelter plant remained on schedule, and by December 1974 the first of three giant smelters was commissioned, making SSPL the first silicon metal producer in Africa. The company, when in full operation at the end of 1975, was expected to produce 32,000 tons of silicon metal annually. The 90,000 tons of silica feed for the smelter was to come from the Whitkop mine. Recoverable reserves from this mine were estimated at 4 million tons of pure quartz, enough to sustain the operation for the next 25 years. The cost of constructing the smelting plant was about $25 million.

Yugoslavia.—The Yugoslavian Economic Organization's (YEO) Jugohrom Company at Jegunovce in southern Yugoslavia continued construction of its ferrosilicon plant. Projected capacity of the plant was increased to 50,000 tons of ferrosilicon from the previously reported 30,000 tons. The completion date was given as the latter part of 1976. Most of the production was to be for export to markets in Europe and Japan.

Total production of ferrosilicon and silicon metal and alloys by Yugoslavia was estimated at 70,000 tons in 1974.

Silver

By Thomas G. Clarke[1]

Domestic mine production of silver decreased 10% from that of 1973 to 33.8 million troy ounces. The decrease, mainly in byproduct metal, was attributed partly to a copper mine strike in Arizona, depressed demand for copper metal, and producer cutbacks in the copper industry. Imports exceeded exports by 115 million troy ounces compared with 119.5 million troy ounces in 1973. The price of silver continued its sharp, upward trend from the close of 1973. On January 2, 1974, the average price was 334.5 cents per ounce, but fell to 327 cents per ounce on January 4, the low of the year. On February 26, the historic high price of 670 cents per ounce was reached during the day, but closed off the peak price by the end of daily trading. Average monthly prices remained in the low $5 range through May, then fell into and remained in the $4 to $5 range for the rest of the year. On December 31, the price was 437 cents per ounce. The average price in 1974 was 470.798 cents per ounce.

Domestic consumption by industry and the arts was 177 million ounces, down 10% from the record high of 196.4 million ounces in 1973. The end-use categories mirrors, batteries, bearings, and catalysts showed significant increases over 1973. Table 9 contains a new reporting category, coins, medallions, and commemorative objects, with appropriate revisions in other data for the years 1972–74. These data were formerly reported in the sterling ware and miscellaneous categories of the end-use table. By the end of 1974, consumption of silver in the coins, medallions, and commemorative objects category had increased to 22.3 million ounces, ranking only below uses in photographic materials and electrical and electronic products categories. Part of the increase since 1973 was attributed to coin blanks fabricated for the Canadian Government to use in its Olympic coin issues. A growing public desire and acceptance for the medallic and commemorative art objects has contributed to a significant increase in consumption.

Industry stocks of silver at yearend were 49.3 million ounces, up 10.9 million ounces from 1973. Treasury bullion stocks in the Bureau of the Mint were 44.03 million ounces at yearend, down 1.1 million ounces, reflecting stocks used in coinage. Silver available to defense contractors from the Defense Department stocks amounted to 6.03 million ounces at yearend. These stocks consisted of fine silver recovered from old scrap items collected mostly from various U.S. military service branches. The total amount of silver in the national stockpile remained at 139.5 million ounces, the same as at yearend 1973. The revised stockpile objective of 21.7 million ounces left 117.8 million ounces as surplus for possible disposal, but Congressional approval is required. During 1974, the General Services Administration (GSA) offered and sold by mail bid, 414,118 silver dollars. These were minted at the Carson City, Nev., mint, which was operated from 1870–93. Of the 2,937,000 Carson City silver dollars originally authorized for sale by GSA, 978,560 silver dollars remained for possible future auction.

Trading volume on the New York Commodity Exchange (COMEX) was 10.62 billion ounces during 1974, a decrease of 1.39 billion ounces compared with that of 1973. The Chicago Board of Trade (CBOT) trading volume was 7.31 billion ounces, a decrease of 0.84 billion ounces from that in 1973. During the year, COMEX warehouse stocks increased 3.5 million ounces to 67.8 million ounces. CBOT stocks decreased 7.9 million ounces to 19.5 million ounces at the end of 1974.

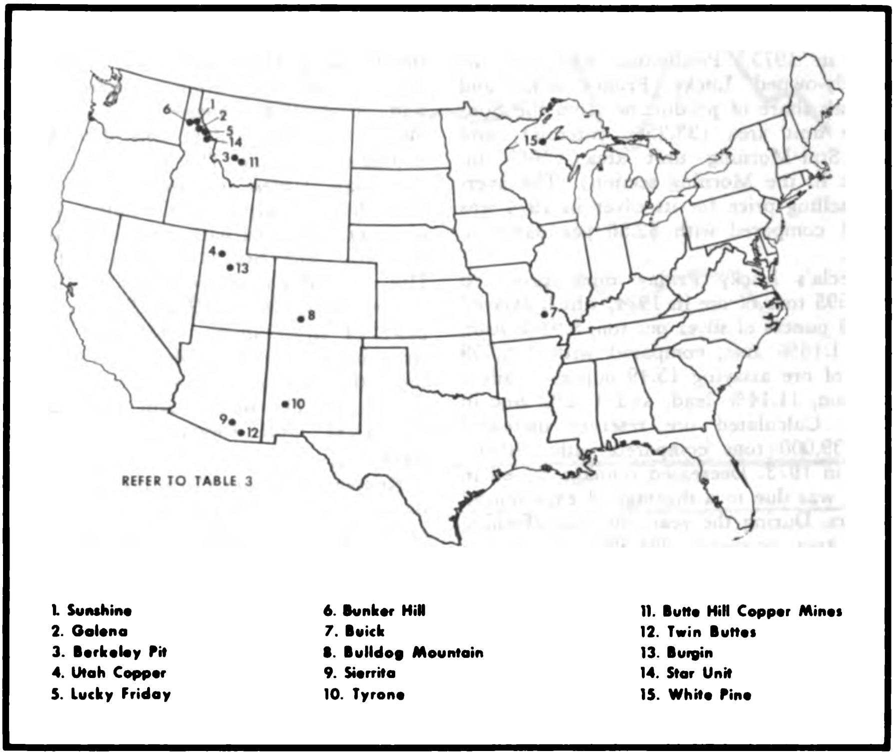

Figure 1.—Major U.S. silver-producing mines.

Legislation and Government Programs.—Legislation was introduced in Congress, but not enacted, to authorize the disposal of 117.8 million ounces of excess silver in the national stockpile.

Silver remained eligible for exploration assistance of up to 75% of approved costs under a program conducted by the Office of Minerals Exploration (OME), U.S. Geological Survey. A few contracts were active in the first half of 1974. No funding was available in the fiscal year 1975–76.

DOMESTIC PRODUCTION

Domestic mine production of recoverable silver was 33.76 million ounces, 3.72 million ounces less than in 1973. A copper mine strike of 1 month, a 2-week shutdown of a mine in Idaho for shaft repairs, and a shortage of skilled miners accounted for much of the decrease in output. Mine production from more than 300 domestic producers was in Idaho, 37%; Arizona, 19%; Montana, 10%; Utah, 10%; Colorado, 8%; Missouri, 7%; New Mexico, 3%; other States, 6%.

The 25 leading silver producers (table 3) accounted for 85% of domestic production. Three of the leading producers mined predominantly silver ores, while the remaining ones mined copper, lead, and zinc ores. Eight of the leading mines produced in excess of 1 million ounces each during the year. Domestic mine production provided 19% of the silver consumed by industry and the arts during 1974.

The Hecla Mining Co., located in the

Coeur d'Alene silver district of Idaho, reported production of 3.58 million ounces of silver, down 0.32 million ounces from that in 1973.[2] Production was from its wholly-owned Lucky Friday mine and Hecla's share of production from the Sunshine unit area (33.25% interest), and the Star-Morning unit area (30% interest in the Morning section). The average selling price for its silver in 1974 was $4.71 compared with $2.56 per ounce in 1973.

Hecla's Lucky Friday mine produced 165,695 tons of ore in 1974, which assayed 13.53 ounces of silver per ton, 9.93% lead, and 1.18% zinc, compared with 176,859 tons of ore assaying 15.49 ounces of silver per ton, 11.14% lead, and 1.22% zinc in 1973. Calculated ore reserves increased to 539,000 tons compared with 510,000 tons in 1973. Decreased tonnage mined in 1974 was due to a shortage of experienced miners. During the year, the Star-Morning unit area produced 281,580 tons of ore compared with 265,781 tons in 1973. Hecla's share was 84,474 tons containing 2.45 ounces of silver per ton, 4.77% lead, and 6.04% zinc compared to 69,734 tons in 1973 assaying 2.79 ounces of silver per ton, 5.18% lead, and 6.68% zinc. Computed ore reserves increased to 336,000 tons compared with 286,000 tons in 1973. Development of the 7,700-foot level, the deepest of the mine, began in early 1974.

The Sunshine Mining Co., operator of the Sunshine unit area, and the nation's leading silver producer in 1974, had an output of 3,845,759 ounces of silver and 445 short tons of antimony concentrate. The Silver Dollar Mining Co. and Hecla Mining Co. each received shares of the Sunshine output.

The Galena mine, also located in the Coeur d'Alene, was the second largest domestic producer in 1974. It was operated by the American Smelting and Refining Company (ASARCO Inc.) and produced 3.49 million ounces of silver compared with 4.19 million ounces in 1973. Production declined due to a shortage of underground labor and a flood on the surface. In June, ASARCO began equipping a new silver mine, the Coeur Shaft Project. Productive capacity was planned at 2.2 million ounces of silver per year and underground development work was proceeding. A new 450-ton-per-day milling facility is scheduled for completion in 1976.

Development work resulted in increased reserves of proven ore at the Bunker Hill and Star mines of the Bunker Hill Co. in the Coeur d'Alene district of Idaho.[3] In 1974, production from company-owned and -controlled mines was 2.2 million ounces of silver, 31,000 tons of lead, and 43,000 tons of zinc. The Bunker Hill mine, the sixth largest domestic producer in 1974, had an output of 1.57 million ounces of silver compared with 2.6 million ounces in 1973. The Star Unit Mine (Bunker Hill and Hecla) produced 0.64 million ounces of silver in 1974. The increased price of silver during the year allowed the mining of lower grade ore so as to extend the life of known reserves of unmined ore. The Bunker Hill Co. is a subsidiary of Gulf Resources & Chemical Corp.

Kennecott Copper Corp. processed 62.09 million tons of copper ore in 1974 and recovered 3.62 million ounces of byproduct silver.[4] This compared with 4.2 million ounces from 66.5 million tons of ore in 1973. Due to severe weather conditions in early 1974, lower grade ore was mined in some areas. Equipment problems in milling and smelting caused substantial losses in production throughout the Metal Mining Division.

The Anaconda Company reported the production of 197,543 tons of copper from which 3.57 million ounces of silver was extracted as a byproduct.[5] In 1974, a growing worldwide surplus of copper and domestic economic recession prompted Anaconda and other U.S. producers to cut base metal prices and curtail production and work force requirements.

Day Mines, Inc. of Wallace, Idaho, owns, leases, or operates approximately 19,000 acres of mining properties in Idaho and Washington.[6] In 1974, silver production from all Day Mines sources amounted to 796,137 ounces, a decrease of 39.5% from 1973 output. Day Mines completed the initial phase of a long-range exploration program designed to strengthen its position as a silver producer.

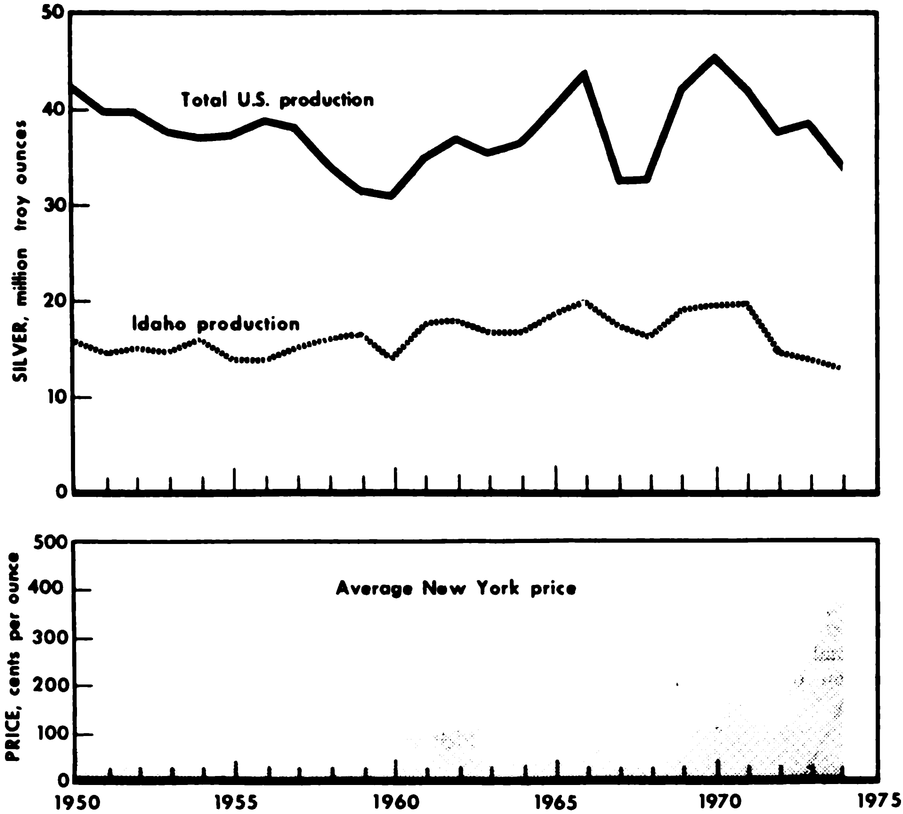

Figure 2.—Silver production in the United States and Idaho and price per ounce.

CONSUMPTION AND USES

Total silver consumed by domestic industry decreased 10% to 177 million ounces in 1974. Significant increases in end uses were reported in mirrors (53%) and catalysts (22%). Moderate increases were evident in commemorative uses, 12%; bearings, 11%; and batteries, 1%. The category of coins, medallions, and commemorative objects has shown expanding usage since 1972.

Six end use categories consumed 86% of the total silver: Photography, 28%; electrical contacts and conductors, 18%; coins and commemorative objects, 13%; sterling ware, 12%; brazing alloys, 8%; and electroplated ware, 7%. The use of silver in coinage increased slightly to 1.02 million ounces compared with 0.92 million ounces in 1973. Silver consumed in coinage was used in the production of proof and uncirculated Eisenhower 40% silver dollars, which were sold to numismatists at premium prices.

Silver used in X-ray film was reported to have declined 10% in 1974 because of high silver prices and improved technology.[7] X-ray film accounted for about 50% of the silver consumed by the photographic industry. The higher price in 1974 also resulted in a greater effort toward silver recovery from spent photographic solutions. Recovery was reported to have been improved to a 90% to 95% rate compared with an 80% rate in 1972.

A new laser-beam recorder using a dry

---

[7] American Metal Market. Silver Consumption for X-ray Films Expected to Decline Again in 1975–76. V. 82, No. 127, July 1, 1975, p. 9.

film for computer printout data was developed by Minnesota Mining & Manufacturing Co. This method recorded computer data on a low-cost dry silver microfilm plate instead of conventional computer paper. The images were expected to remain reproducible for up to 25 years. The laser-beam method was an improvement over an earlier COM (computer-output-microfilm) system, which used a wet film process.[8]

American Water Purification, Inc., reported development of a unit containing silver which disinfects the circulating water of a swimming pool.[9] The disinfection involved the combination of the free silver ions in water with the sulfhydrol groups in the enzyme systems of waterborne bacteria, which, when within the cells, blocked the transfer of hydrogen and killed the bacteria. This silver purifier was reported to control both algae and bacteria.

Long-life silver bearings for the thrust reversers of jet planes were developed.[10] These bearings function smoothly under severe pressures and at temperatures up to 1,400° F. Nonsilver bearings used as jet thrusters normally had been replaced after 500 hours of service. The new bearings are made from silver powder, which is combined with smaller amounts of aluminum oxide, phosphate, barium, and calcium fluoride.

STOCKS

The Treasury bullion stock outflow in 1974 was 1.1 million ounces, all of which was consumed in the production of the Eisenhower 40% silverclad dollar. Yearend Treasury stocks were 44.03 million ounces and consisted of bullion, coin bars, and coinage metal fund silver.

Total accountable stocks were 326.2 million ounces. These consisted of 49.3 million ounces in industry stocks, 44.03 million ounces in Treasury stocks, 6.03 million ounces in Department of Defense stocks, 139.5 million ounces in the strategic stockpile, and 87.3 million ounces in COMEX and CBOT registered vaults. Total yearend stocks were up 5.4 million ounces over those in 1973.

PRICES

New York silver prices in 1974, as quoted by Handy & Harman, ranged from a low of 327 cents per ounce on January 4 to a historic high of 670 cents per ounce on February 26 (fig. 2). Average monthly prices declined thereafter until September, when the price stabilized, then remained in the $4 to $5 range for the rest of the year. The average price of silver in 1974 was 470.798 cents per ounce compared with 255.8 cents per ounce in 1973, an increase of 84%.

Worldwide inflation along with domestic recession caused fluctuations in international exchange rates, which resulted in speculative demand for silver. Also, because silver prices were at substantially higher levels than in 1973 and most price increases were passed through to finished products, demand was less for many items.

Prices on the London Silver Market ranged from a low of 328.172 cents per ounce to a high of 723.738 cents per ounce (U.S. equivalent). The average 1974 price was 467.458 cents per ounce, slightly less than the New York average.

Prices continued to advance sharply on silver futures commodity trading exchanges. The trading volume on COMEX was 10.62 billion ounces, a decrease of 1.39 billion ounces from the 1973 volume. On CBOT, trading volume was 7.31 billion ounces, a decrease of 0.84 billion ounces from that in 1973. COMEX announced a reduction of the contract trading unit to 5,000 ounces from 10,000 ounces, effective September 27. Thus, the trading unit on both exchanges was 5,000 ounces from that date.

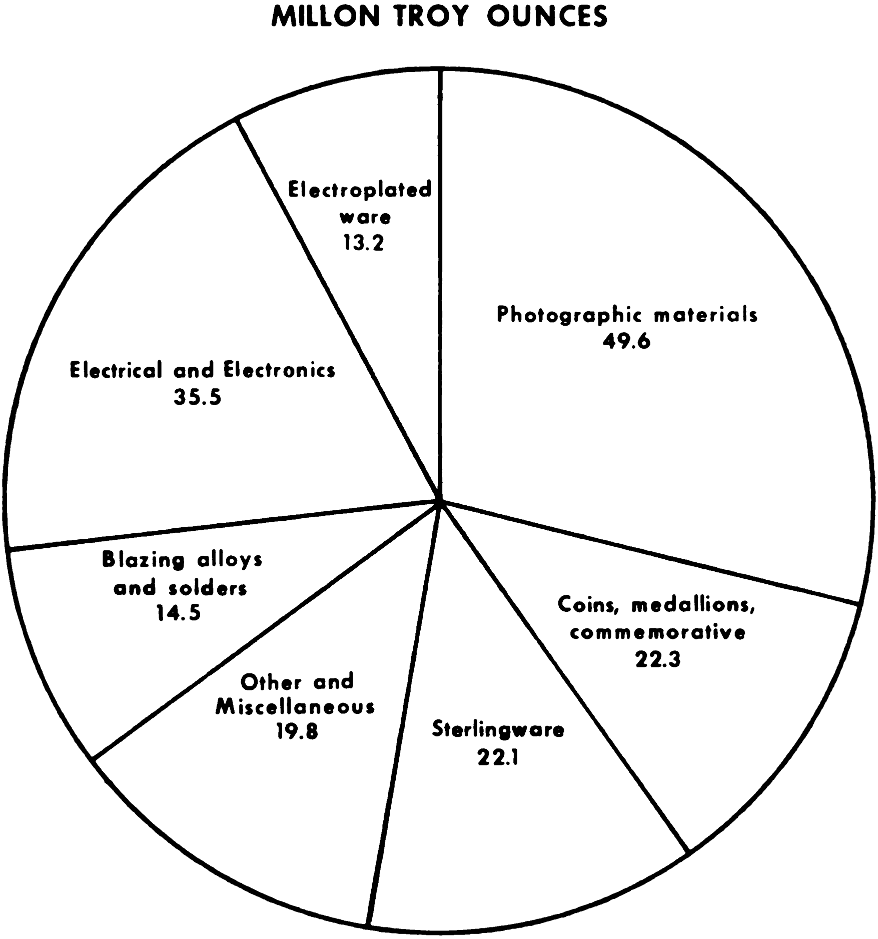

Figure 3.—Silver consumption in the United States, 1974.

FOREIGN TRADE

Exports of silver increased 64% to 18.4 million ounces in 1974. Canada received 45% of total exports; the United Kingdom, 18%; Belgium-Luxembourg, 14%; Japan, 11%; and West Germany, 3%. The remaining 9% went to 14 other countries. A small quantity of silver in ore and concentrates went mostly to West Germany and Canada. Canada, the United Kingdom, and Belgium-Luxembourg were destinations for most of the waste, scrap, and sweepings. Bullion went mainly to Canada, Japan, Brazil, and the United Kingdom. The bullion imported by Canada from the United States in 1974 was almost 4 times that imported in 1972. Part of this was attributed to an increased use in coinage, mainly that in sterling coins commemorating the 1976 Olympic games to be held in Ottawa, Ontario.

Total silver imports increased 2% to 133.4 million ounces. The main sources of imports were Mexico, 29%; Canada, 27%; the United Kingdom, 14%; Peru, 13%; and Japan, 4%. Other countries supplied the remaining 13%. Refined bullion constituted 67% of total imports. Unrefined silver accounted for 33%.

Net imports decreased to 115 million ounces from 119.5 million ounces in 1973, reflecting reduced demand.

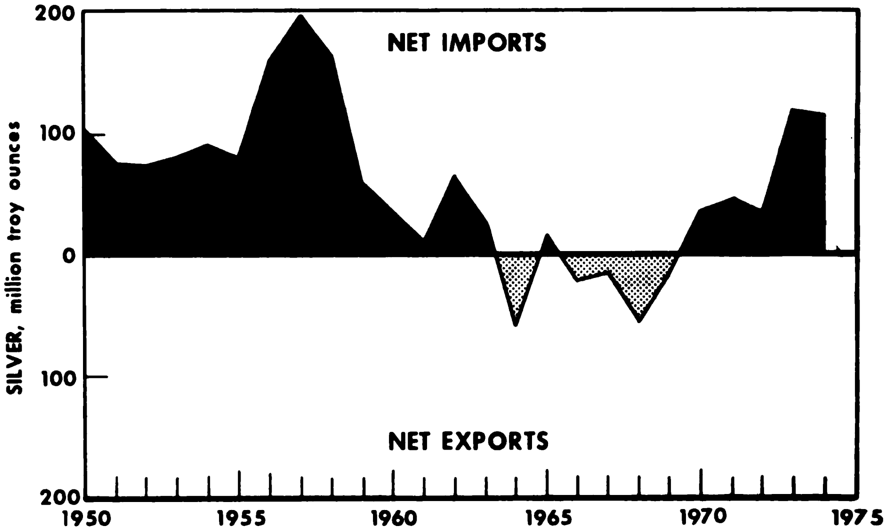

Figure 4.—Net exports or imports of silver, 1950–74.

WORLD REVIEW

World mine production of silver in 1974 was 295.6 million ounces, a decrease of 13.0 million ounces from that in 1973. All major producing countries reported decreases in silver output, partly due to a drop in production of base metals. The Western Hemisphere produced 58% of total world silver mined in 1974.

World consumption of silver in industry and arts decreased to 415 million ounces in 1974 from 472 million ounces in 1973.[11] World coinage, however, increased 12 million ounces, partly because of Canadian production of 1976 Olympic games coin sets. Total consumption by market economy countries exceeded newly mined supply by 175 million ounces, according to Handy & Harman estimates. This supply-demand gap was filled by secondary recovery and liquidation of private and industry stocks.

Australia.—Total silver production was 21.62 million ounces, about 4% less than in 1973. At operations of Mount Isa Mines, Ltd., the country's principal silver producer, production was interrupted during February and March because of surface flooding. Nevertheless, output rose to 9.69 million ounces of silver in 1974 compared with 8.8 million ounces in 1973. ASARCO has a 49% share in Mount Isa Mines, Ltd. Total proven silver-lead-zinc reserves were placed at 56 million tons of extractable ore. The Hilton mine, a silver-lead-zinc deposit owned by Mount Isa, was under gradual development for operation within the next decade. Proven reserves were estimated at 37 million tons of ore. Grade of the ore was unavailable.

The Mount Lyell mine is located in Tasmania and operated by the Mount Lyell Mining and Railway Co., Ltd., a 61% owned subsidiary of Consolidated Gold Fields Australia, Ltd. In 1974, this copper-gold-silver mine produced 3.98 million ounces of silver. Proven reserves were over 30 million tons of ore.

---

[11] Handy & Harman. The Silver Market, 1974. 59th Annual Review. 1974, 23 pp.

The Broken Hill and Broken Hill South mines, both silver-lead mines, produced an estimated 3 million ounces of silver in 1974. Estimated reserves for both mines were about 14 million tons of ore.

Canada.—Primary production of silver in 1974 was 42.1 million ounces, 5.4 million ounces less than the record high of 47.5 million ounces in 1973.

The decrease was attributed mainly to reduced mine output caused by labor shortages and depressed base metal operations. Canada maintained its place as the world's leading producer of silver. The main market continued to be the United States, which imported over 80% of Canada's total output.

The Province of Ontario was the leading source, providing over 40% of all silver mined in 1974. The Kidd Creek mine, located at Timmins, Ontario, probably the world's largest single silver producer, produced 10.55 million ounces from 3.61 million tons of ore. Underground operations during the year were equipped with a shaft 3,000 feet in depth with 400-foot drift intervals. Construction was begun on the headframe of a second shaft to extend 5,300 feet in depth. Additional underground work would enable mine production to be increased to about 5 million tons of ore annually.

Mines 6 and 12 of the Brunswick Mining and Smelting Corp., Ltd., at Bathhurst, New Brunswick, produced 4.99 million ounces of silver in 1974. Extensive exploration and a new shaft to a depth of 4,500 feet increased ore reserves to 84.7 million tons at the beginning of 1974. These reserves averaged 9.38% zinc, 3.84% lead, 0.27% copper, and 2.79 ounces of silver per ton. Open pit operations at the No. 6 mine were expected to be terminated in late 1975.

The Sturgeon Lake, Ontario, mine, operated by Mattabi Mines Ltd., produced 3.41 million ounces of silver from 1.1 million tons of ore. Normal operations were hampered by the lack of experienced miners.

In British Columbia, the Sullivan mine at Kimberly produced 1.69 million ounces of silver. Operations were suspended from July 1 to October 31 owing to a strike.

Silver production in the Yukon Territory was about the same as in 1973. United Keno Hill Mines, Ltd., reported production of 3.24 million ounces from the Husky, Elsa, No Cash, Keno, Towsite, Dixie, and Shamrock mines. The Cyprus Anvil Mining Corp. reported 2.25 million ounces output from its Faro mine. Dynasty Exploration Ltd. and Cima Resources, Ltd., continued exploration work in the Hess Mountains area, 110 miles north of the Ross River. Six significant silver-lead mines and vein exposures were being prepared for diamond drilling and further evaluation.

Significant production was reported by Echo Bay Mines Ltd. from a silver-copper mine located at Port Radium on Great Bear Lake, Northwest Territories. Output was 2.12 million ounces of silver. Echo Bay conducted further explorations on an adjoining property. Terra Mining and Exploration Ltd. N.P.L. produced 1.4 million ounces of silver from its underground mine in the Camsell River area.

Dominican Republic.—At the end of 1974, the Pueblo Viejo gold and silver mining and cyanide leaching facilities were nearing completion.[12] Scheduled to operate at 8,000 tons per day, the open pit mine would be the second largest gold producer in the Western Hemisphere, with annual output of 350,000 ounces of gold and a significant output of silver amounting to 1.5 million ounces. Additional drilling information in 1974 established total oxide ore reserves at 30 million tons grading 0.126 ounce of gold and 0.76 ounce of silver per ton. The operator was Rosario Dominicana, S. A., owned by Rosario Resources Corp. (40%), J. R. Simplot and Co. (40%), and the Central Bank of the Dominican Republic (20%).

Honduras.—The El Mochito mine of Rosario Resources Corp. produced 326,248 tons of ore which graded 11.9 ounces of silver and 0.007 ounce of gold per ton, 7.83% lead, and 8.61% zinc.[13] Output of silver amounted to 3.7 million ounces, 16% higher than in 1973. Ore reserves in the Main and Yojoa areas decreased slightly to 1.73 million tons.

India.—India authorized the uncontrolled export of silver bullion, sheets, and plates beginning on February 17, 1974. A trade source reported that 400,000 ounces of silver were exported from Bombay in the first 5 weeks after legalization. During

---

[12] Rosario Resources Corporation. 1974 Annual Report. P. 7.

[13] Page 5 of reference cited in footnote 12.

1974, exports and consumption for industrial purposes each were estimated at about 27 million ounces. According to reports, individual reserves held by the Indian public constitute one of the world's largest storehouses of silver.

Japan.—Mine production of silver declined to 7.3 million ounces in 1974, a 14% decrease from 1973 output. Industrial consumption was about 55 million ounces, down 20% from the record high in 1973.[14] No silver was used in coinage. To fill the supply/demand gap, Japan imported about 29 million ounces of silver, mainly from Peru, Mexico, and Australia. Exports were 7.5 million ounces compared with 0.15 million ounces in 1973.

Mexico.—Mine production from Mexico, the world's third largest silver producer, was 37.5 million ounces in 1974, 1.24 million ounces less than that in 1973. Industrias Peñoles, S.A., one of Mexico's two large producers, announced that the discovery of four important new areas for prospecting, along with development of existing areas, would establish Mexico as the world's leading silver producer in 1976. Mexican output in 1976 was projected close to 60 million ounces. Government stocks were estimated at about 8 million ounces at the end of 1974.

Pure Silver Mines Ltd. reported completion of a feasibility study on a 2,000-ton-per-day operation based on proven reserves of about 3.6 million tons of silver-gold ore. Approximately $9 million had been spent on a joint exploration project by Cia. Minera Fresnillo, S.A., and Industrias Peñoles, S.A. (70%), and Pure Silver Mines (30%).

In the Durango area, Minas de San Luis, S.A., reported exploration activity in the La Libertad mine. Several new levels were opened as a result of diamond drilling. Approximately 200,000 tons of ore on or near the Santa Rosa vein were blocked out. The average ore grade was 16.1 ounces of silver and 0.03 ounce of gold per ton. The width of the vein varied between 3 and 8 feet. Preliminary flotation tests indicated a gold and silver recovery rate of 80%.

Tormex Mining Developers reported that the La Encantada mine ore was being milled at the rate of 500 tons per day. Construction and most development were completed in 1974. The main operation was the mining of lower grade ore from the upper levels, which contained 20% lead and 6 ounces per ton in silver. Earlier development indicated La Encantada higher grade ore averaged 40% lead and 30 ounces per ton in silver.

Rosario Mexico, S.A. de C. V., operated the Huautla mine at Morelos. This silver-lead operation was 40% owned and operated by Rosario Resources Corp. With production initiated in 1971, the Huautla project currently contains reserves of 396,224 tons, averaging 19.3 ounces per ton in silver. A new shaft and expanded milling facilities were expected to be completed at the end of 1976.

Industrial Minera Mexico, S.A. (formerly ASARCO Mexicana, S.A.), a subsidiary of American Smelting and Refining Company, had a refinery output of 20.7 million ounces of silver in 1974. Mine and plant production provided an increase of 3.5 million ounces of silver over that of 1973. Operations at the mines were normal and ore reserves were increased at the various mining units, except at the Parral mine, where operations ceased in March 1975 for lack of minable ore.

In April ASARCO Mexicana completed the sale of a part of its capital stock in Industrial Minera Mexico, S.A., to Mexican investors, thus reducing its equity to 34% from the 49% formerly owned.[15]

Nicaragua.—Rosario Mining of Nicaragua, Inc., reported intensified exploration efforts in the La Luna area, located about 15 miles from Zeldya. Approximately 1.13 million tons of proven and probable ore reserves averaged 0.087 ounce of gold and 4.39 ounces of silver per ton. Diamond drilling was continuing to develop additional gold-silver reserves.[16]

Peru.—Peru maintained its position as the second largest silver producer in 1974. Mine production was 41 million ounces, down about 1 million ounces from 1973. Silver produced in Peru was a byproduct of base metal production, mainly copper.

The Cerro Corp. announced that its subsidiary, Cerro de Pasco Corp. was expropriated on January 1, 1974, by the Peruvian Government.[17] Negotiations were concluded successfully by an emissary of the U.S. Government. The Cerro Corp. stated that Cerro de Pasco received a cash payment of $67 million covering partial compensation for the company. The Cerro Corp. intended to continue its commercial relationship with the Government of Peru. It expected to provide purchasing services to Empresa Minera del Centro del Peru, the Peruvian marketing organization and successor to Cerro de Pasco.

Financing for the Cuajone copper project of Southern Peru Copper Corp. was completed in July 1974.[18] The Cuajone project reached about 65% completion by yearend. When completed, the facility will have an annual capacity of 170,000 short tons of blister copper and a substantial quantity of byproduct silver.

TECHNOLOGY

Researchers at the Bureau of Mines Reno Metallurgy Research Center conducted investigations of improved processes for recovering silver from low-grade and refractory ores. Techniques were expected to be applicable to deposits not large enough to justify the capital expenditure required for conventional processing. Research continued on methods of desorbing silver and gold from activated carbon using alkaline alcohol solutions. An improved chloridizing roasting-cyanidation process sequence for the recovery of silver from a complex refractory ore containing silver-bearing jarosite and manganese minerals appeared promising. Also, an improved procedure was developed for chloridizing silver ore at modest roasting temperatures. A 90% silver extraction was attained using cyanidation on calcines, which had been chloridized at 400° C in an airstream saturated with water vapor.

The Bureau of Mines released a report on its continuing ground support studies in the Coeur d'Alene silver district of Idaho.[19] The report described fieldwork and analyses necessary to determine physical properties, stress distribution, and other aspects of rock behavior for the evaluation of support requirements for a typical mine opening. The work was conducted in the Crescent mine near Wallace, Idaho. Conventional overcore techniques with a three-component borehole deformation gage developed by the Bureau were used in three drill holes. The overcore theory, which predicts that a similar deformation effect occurs in the wall rock around the perimeter of an opening in rock under stress, was sustained upon analysis of overcore rock samples.

Hecla Mining Co. developed an improved method to prevent dust from blowing over surrounding areas from filled tailing ponds. Most of the liquid waste pumped into the ponds consisted of silt and smaller suspended fractions. An asphalt emulsion was applied to the surface which was stabilized as the water evaporated. Vegetative cover was compatible with the asphalt emulsion, further limiting future dust problems.

A Japanese firm developed a new method of recovering silver from spent color photographic solutions. Developing solutions which had lost their ability to develop film because of a build-up of silver and iron were treated with either iron sulfide or cobalt sulfide. The dissolved silver and iron were recovered, permitting reuse of the developing solution. The developing time was increased 10 seconds over that of a newly prepared solution.

An improved silver solder alloy, which provided better solder connections in the manufacture of ceramic capacitors, was developed by a Japanese metal company. The solder consisted of silver, cadmium, tin, and lead. The low melting point (about 392° F) allowed soldering of the electrodes at low temperatures without cracking of the ceramic. Silver in the alloy also reduced the tendency of the solder to dissolve the silver electrodes attached to the capacitor.

---

[1] Prices are as follows:

1874–1917:	Asked price per fine ounce (unrefined).
1918–29:	Mean of bid and asked prices per fine ounce (unrefined).
1930–61:	Official quotations per ounce 999/1000 fine (unrefined).
1962–66:	Official quotations per ounce 999/1000 fine (refined). Quotations for refined silver are one-fourth cent above prices for unrefined silver.

[2] The price of $1.293 per ounce was effective continuously from September 9, 1963, through May 18, 1967.

NOTE.—There was no open-market price of silver as such in the United States under the bimetallic monetary standard which existed from April 2, 1792, until February 12, 1873. The ratios of the silver dollars to the gold dollar in this period were as follows:

Act of—	Ratio of silver to gold
April 2, 1792	15 to 1
June 28, 1834	16.002 to 1
January 18, 1837	15.988+ to 1

Source: Annual Report of the Director of the Mint, Washington, D.C.

Table 11.—Value of silver exported from and imported into the United States
(Thousand dollars)

Year	Exports	Imports
1972	49,260	101,580
1973	27,638	330,456
1974	81,651	623,794

e Estimate. p Preliminary. r Revised.

[1] Recoverable content of ores and concentrates produced unless otherwise noted.

[2] In addition to the countries listed Bulgaria, Thailand, Turkey and several African countries produce silver, but information is inadequate to make reliable estimates of output levels.

[3] Less than ½ unit.

[4] Includes production by the State mining company (COMIBOL) plus the exports of medium and small (private sector) mines.

[5] Smelter and/or refinery production.

[6] Partly estimated on the basis of silver content of lead ores exported.

[7] Output of Inyati mine only.

[8] Data represent recoverable content of Tsumeb Corp. Ltd. concentrates as well as recovery from copper refinery sludges.

[9] Includes estimate for Klein Aub Koper Maatskappy Ltd.

[10] Includes recovery from copper refinery sludges.

Slag—Iron and Steel

By Harold J. Drake [1]

Processing of iron slag was at a higher level in 1974 than in 1973 despite lower production of pig iron at yearend. The lower output of processed steel slag was more in line with the decrease in steel production that occurred in 1974. Combined output of both types of slag was up 0.5% in quantity and 8% in value over 1973 levels. Production of iron slag rose 4% in quantity and 8% in value, whereas that of steel slag decreased 9% in quantity but increased 4% in value. The trend in recent years toward less processing (other than crushing and screening) continued; tonnage of screened, air-cooled iron slag rose 8%, whereas tonnage of granulated and expanded iron slag declined 5%.

A 5% price increase was recorded for iron slag and a 14% increase for steel slag. Despite price increases, iron and steel slags continued to be strongly competitive with similar construction materials. A sharp gain in exports was recorded; volume rose 40% and value more than tripled. No imports of slag were reported in 1974.

DOMESTIC PRODUCTION

The volume of iron slag processed in 1974 totaled 29.9 million tons valued at $68.1 million, compared with 28.8 million tons valued at $62.9 million in 1973. Production of the principal type of iron slag—screened, air-cooled slag—totaled 25.6 million tons valued at $56.4 million, which represented gains of 8% and 11%, respectively, over the production and value levels of 1973. However, output of unscreened, air-cooled material, was nearly halved. Of the approximately 12% of iron slag processed using water techniques, granulated slags rose slightly to 2.1 million tons valued at $4.4 million, whereas expanded slags declined moderately to 1.6 million tons valued at $6.5 million. A portion of the increased output of processed iron slag came from stockpiles. A decline in output at steel operations led to a 9% decline in steel slag to 8.9 million tons. However, the value of steel slag rose 4% to $11.2 million.

A total of 60 companies reported operating 91 air-cooling, 9 expanding, and 10 granulating slag plants in 1974. Slag-encrusted iron reclaimed magnetically by slag processors for resmelting totaled 3,761,000 tons. The 1,551 plant and yard employees in the industry worked a total fo 2,088,545 man-hours.

About 20% of all slag was produced in Pennsylvania, another 20% in Ohio, and another 20% in Illinois, Indiana, and Michigan. The remaining 40% came from a number of States, including Alabama, California, Maryland, and New York.

CONSUMPTION AND USES

As in past years, nearly all of the slag produced in the manufacture of pig iron and steel was either recycled or used by the construction industry.

An 8% increase in consumption of screened, air-cooled, iron slag was accounted for principally by a 14% increase in shipments for highway and airport construction, a 24% increase in shipments for railroad ballast, and an 18% increase in use for portland-cement concrete construction. Together, these uses accounted for 70% of the total consumption of this type of iron slag. Significant uses that recorded declines were bituminous construction, 6%; concrete block, 31%; mineral wool, 24%; and roofing material, 26%. Consumption of unscreened, air-cooled iron slag was halved, primarily because demand was greater for screened material. The principal use, highway and airport construction, recorded a 13% decline, and numerous other minor applications nearly disappeared.

The volume of granulated and expanded iron slag consumed in construction declined 1.5%. An increase of 4% for granulated slag was offset by a 15% decrease for expanded slag. In its principal use, highway construction, granulated slag was down 2%. In the principal use for expanded slag, concrete block manufacture, consumption was down 16%. Other uses for granulated slag, such as cement and concrete block manufacture, recorded gains. All significant uses of expanded slag recorded declines.

Consumption of steel slag was 9% below that of 1973 and was characterized by sharp fluctuations throughout its range of uses. Use as highway base, railroad ballast, and bituminous mixes was nearly halved in 1974, and significant increases in use as base and fill material, in agriculture, and other applications were not sufficient to offset these losses. More efficient utilization of steel slag was reported in a paper that discussed production and disposal of both iron and steel slags.[2]

A series of rapid wet-chemical methods for the analysis of iron slags was described.[3]

PRICES

Slag producers reported generally rising prices in 1974 in nearly all slag applications. The overall average f.o.b. plant price for iron slag rose from $2.18 per ton in 1973 to $2.28 per ton in 1974. Similarly, the price of steel slag rose from $1.11 per ton to $1.26 per ton.

The average price of screened, air-cooled iron slag in 1974 was $2.20 per ton compared with $2.14 per ton in 1973. For aggregate use, the average price rose 2% to $2.26 per ton; for railroad ballast, 7% to $1.69 per ton; and for mineral wool, 4% to $2.49 per ton. A 19% decline in the price of unscreened slag used for highway construction was recorded in 1974.

The average prices of granulated and expanded slags were 16% and 10% higher, respectively, than those of 1973. The price of granulated slag used in highway and airport construction, the principal use, rose 20% to $1.64 per ton, whereas prices for other major uses generally declined. Price declines were recorded for expanded slag in most of its uses.

Price increases for steel slag ranged from 4 cents per ton to $1.58 per ton in 1974. For base and fill use, which accounted for about 79% of the total use, the increase averaged 16 cents per ton. The price of steel slag used for ballast rose 11 cents to $1.37 per ton.

FOREIGN TRADE

Exports of iron and steel slag increased sharply to 51,902 tons valued at $2.5 million. Nevertheless, exports were equivalent to only 0.1% of the quantity and 3% of the value of domestic production of slag.

The high unit value for exported slag, $48.63 per ton on the average, were indicative of the high metal content of the material. Increased exports to Canada and Mexico accounted for nearly all of the increase in quantity and value of exports. About 95% of the exported material went to these two countries; Canada alone accounted for 72%. Other countries receiving significant quantities were Belgium-Luxembourg, the United Kingdom, and Australia.

Imports of slag in 1974, if any, were not reported in official statistics.

Sodium and Sodium Compounds

By Charles L. Klingman [1]

A general slowdown of the economy in 1974 decreased demand for soda ash. Outputs of the two major consuming industries, glass and paper, were considerably below normal. Natural soda ash production, derived from Wyoming trona, continued to gain but not as rapidly as predicted; gains were offset by losses in production of synthetic (Solvay) soda ash. Exports of soda ash hit an alltime high at 7.5% of the U.S. production. Sodium sulfate was in moderate demand throughout the year in spite of a 6.6% increase in production, probably because of larger amounts of sodium sulfate in soap and detergent formulations. Imports of sodium sulfate increased from 20% to 22% of the U.S. supply.

Prices for both soda ash and sodium sulfate increased by more than a third during 1974 because of sharply increased costs of fuels, raw materials, and labor.

Major enlargements in production capacity for natural soda ash were continuing, which should increase natural soda ash output 85% by 1978. Overcapacity will probably be avoided, however, by decreases in Solvay production and by development of an active export trade.

Caustic soda, which was interchangeable with soda ash in some applications, was in short supply during the latter part of 1974 because of decreased demand for its coproduct, chlorine. Soda ash was needed to substitute for caustic soda in some instances.

Legislation and Government Programs.—A tax benefit, the depletion allowance, was denied in 1971 to producers of natural soda ash who used "decarbonation" to purify their products. This step of soda ash production was ruled to be processing rather than mining. In 1974, however, the tax benefit was restored to soda ash producers by Public Law 93–499 in which the term "mining" was redefined to include decarbonation.[2]

Federal control of prices of sodium compounds was discontinued April 1, 1974.

DOMESTIC PRODUCTION

The total quantity of soda ash produced in 1974, the sum of both natural and synthetic, was almost identical to that of 1972 and 1973 at 7,561,000 short tons. Natural soda ash production increased 9%; synthetic decreased 8%; and the fraction of soda ash coming from natural sources increased from 49% in 1973 to 54% of the total in 1974. A general economic slowdown in 1974, coupled with higher soda ash prices, had a softening effect on demand.

There were five synthetic soda ash plants in the United States with a combined capacity of about 3.25 million tons per year. Synthetic soda ash required much more energy per ton of output than did the natural product; the current energy shortage, coupled with higher energy prices, put the Solvay plants at an economic disadvantage.

[3] Includes Glauber's salt.

Total production capacity for natural soda ash plants in 1974 was about 4.6 million tons per year. In the second quarter of 1975, two major expansions are scheduled: An increase of 1.1 million tons per year by Allied Chemical Corp. and 0.8 million tons per year by FMC Corporation, thereby increasing the national total to 6.5 million tons per year. In the third quarter of 1977, two additional increases in capacity are due to come onstream—Kerr McGee's new plant at Searles Lake, Calif., at 1.3 million tons per year, and Texasgulf Inc.'s new plant at Granger, Wyo., at 1.0 million tons per year. When the new plants are in operation, U.S. production capacity for natural soda ash will be 8.5 million tons per year, 85% greater than that of 1974. Stauffer Chemical Co. is said to be planning further increases in capacity, but no formal announcement has been made.

It might have appeared that the industry was building toward overcapacity, but two conditions were likely to keep the supply and demand in balance. First, it was probable that there will be further reductions in Solvay soda ash production because of its unfavorable economics and pollution problems; second, there will probably be an increase in world demand for soda ash and, consequently, an active export trade from the United States.

At the end of 1974, soda ash stocks were quite low, and it was estimated that several months would be required to build inventories back to normal levels.[3]

Some of the natural soda ash plants in Green River, Wyo., were curtailed in their use of natural gas and had to change to fuel oil for processing heat.

There was a 6.6% increase in total U.S. sodium sulfate production in 1974, and most of this increase occurred in manufactured, rather than in natural, salt cake. Naturally derived sodium sulfate sold or used comprised 49% of the total as compared with 51% in 1973. In the past, natural salt cake had shown a growth rate of about 5% per year. Natural sodium sulfate was produced by four companies at six plants located in California, Texas, and Utah.

---

[3] Chemical and Engineering News. All Signs Point to a Good Year for Soda Ash. V. 53, No. 8, Feb. 24, 1975, p. 11.

Ozark-Mahoning Co., which operated two salt cake plants in Texas, was purchased by the Pennwalt Corp. Kerr McGee Chemical Corporation, which operated one of the plants at Searles Lake, Calif., purchased its neighbor plant from the Stauffer Chemical Co.[4] Kerr-McGee was in the process of building a new plant on Searles Lake that was scheduled to start producing, among other products, about 400,000 tons per year of sodium sulfate by the end of 1977. Foote Mineral Company of Kings Mountain, N.C., was scheduled to complete a new lithium carbonate plant in 1976 that was designed to produce about 18,000 tons per year of byproduct sodium sulfate.

The FMC Corporation rayon plant at Parkersburg, W.Va., was closed in October 1974 with an attendant loss of 22,000 tons per year of byproduct sodium sulfate.[5]

Metallic sodium production dropped 2% to 173,212 tons in 1974 probably due to decreased demand in the tetraethyl-lead industry where most of the metallic sodium is used. A list of U.S. producers of natural sodium compounds and metallic sodium follows:

Product and company	Plant location	State	Source of sodium
Soda ash:			
Kerr McGee Chemical Corporation	Trona	California	Dry lake brine.
Do	Westend	do	Do.
Allied Chemical Corp	Green River	Wyoming	Underground trona.
FMC Corporation	do	do	Do.
Stauffer Chemical Co	do	do	Do.
Sodium sulfate:			
Kerr-McGee Chemical Corp	Trona	California	Dry lake brine.
Do	Westend	do	Do.
United States Borax & Chemical Corp	Boron	do	Open pit mining.
Ozark-Mahoning Co	Brownfield	Texas	Subterranean brine.
Do	Seagraves	do	Do.
Great Salt Lake Minerals & Chemical Corp.	Ogden	Utah	Salt lake brine.
Metallic sodium:			
E. I. du Pont de Nemours & Co	Niagara Falls	New York	Salt.
Do	Memphis	Tennessee	Do.
Ethyl Corp	Baton Rouge	Louisiana	Do.
Do	Houston	Texas	Do.
Reactive Metals Inc	Ashtabula	Ohio	Do.

CONSUMPTION AND USES

Normally more than half of the U.S. soda ash and about 5% of the sodium sulfate consumption goes to the glass industry, but during the latter part of 1974 there was a slump in ordinary glass production, especially in flat glass for the building industry and for automobile glass. Reduction in these fields was estimated to be at least 35%.[6] Production of glass for containers was also down about 10%, so the demand for soda ash and sodium sulfate in glass was reduced proportionately. Production of pulp and paper was estimated to be reduced 20% in 1974, but the soda ash and sodium sulfate consumption for this end use held up well because of the shortage of caustic soda, which is interchangeable with soda ash in the pulping process.[7]

The soap and detergent industry continued to grow at its customary 4% to 5% per year rate, and it consumed proportionately more soda ash and sodium sulfate. Reduction of phosphates in soap formulations for ecological reasons required the use of more soda ash and sodium sulfate.

Production of chlorine-caustic soda is of significance because of the interchangeability of soda ash and caustic soda. Toward the end of 1974, there was a sharp drop in demand for chlorine because of declines in chlorinated solvents, chemicals, and paper products. This reduced the availability of caustic soda, a coproduct of chlorine production and allowed soda ash to penetrate caustic soda markets.

[6] Chemical Marketing Reporter. Soda Ash Markets Softening; Makers Expect Future Growth. V. 207, No. 8, Feb. 25, 1975, p. 16.

[7] Work cited in footnote 6.

One developing application for soda ash was the reduction of sulfur pollution in stack gases, primarily in powerplants and other large furnaces. Powdered soda ash was injected with the fuel after which it reacts with sulfur dioxide, or other sulfur-bearing gases, to form solids such as sodium sulfite. These solids may be removed from the exhaust gases by filters or precipitators.

Production of tetraethyl lead and tetramethyl lead required the use of metallic sodium in their manufacture. Demand for antiknock compounds was off 9% in 1974 as compared with a 2% reduction in demand for metallic sodium. From these figures, it might be inferred that losses from the manufacture of antiknock compounds were offset by increases in other applications of metallic sodium such as reduction of metallic ores and in the manufacture of detergents.

PRICES

Average producer prices for soda ash rose by 34% in 1974 from $25.36 per ton in 1973 to $33.87 per ton in 1974. Actual prices, as quoted, were somewhat higher.[8]

Average producer prices for sodium sulfate rose by 39% from $17.26 per ton in 1973 to $23.99 per ton in 1974.

Similar producer prices were not surveyed by the Bureau of Mines for metallic sodium, but prices quoted in the Chemical Marketing Reporter indicated no change in 1974. Market prices quoted at yearend for sodium compounds were as follows:

	1973	1974 [1]
Sodium carbonate (soda ash):[2]		
Light, paper bags, carlots, works ---- per ton --	$49.50	$56.00–$74.00
Light, bulk, carlots, works ---- do ----	35.50	54.00– 64.00
Dense, paper bags, carlots works ---- do ----	49.50	42.00– 42.50
Dense, bulk, carlots, works ---- do ----	35.50	42.00– 54.00
Sodium sulfate (100% Na_2SO_4):		
Technical detergent, rayon-grade, bags, carlots per ton --	43.00– 46.00	43.00– 46.00
Technical detergent, rayon-grade, bulk works do ----	33.00	33.00– 38.00
Domestic salt cake, bulk, works[3] ---- do ----	28.00	31.00
National Formulary (N.F. XII), drums per pound --	.23½	.23½
Metallic sodium:		
Bricks, carlots, works ---- do ----	.30	.30
Fused, lots 18,000 pounds and more, works - do ----	.26½–.27½	.26½–.27½
Bulk, tank, works ---- do ----	.18¾	.18¾

[2] Soda ash prices for 1973 converted from pounds to tons for comparability.

[3] East of Mississippi River; price in the west is $18.50 per ton, f.o.b. producing point.

FOREIGN TRADE

In 1974, exports of soda ash increased to an alltime high of 7.5% of the total U.S. production or 564,000 tons. Slackened demand in the United States and the worldwide shortage of soda ash provided double impetus for the large export trade. Over half of the export went to North American countries; about one-fourth, to South American countries; and one-fifth, to Asiatic and Oceanic countries. There was a small (0.5%) amount of soda ash imported.

The United States imported 22% of its sodium sulfate supply and exported 3%. About 64% of the imports came from Canada, and nearly all the rest came from Belgium-Luxembourg. About one-fourth of the exports went to Canada and Mexico; 28%, to Australia; and 34%, to Asiatic countries.

The value of exports of sodium compounds exceeded the value of imports by over $23 million.

Tariff rates for imported sodium compounds in 1974 are shown in the following tabulation:

	Tariff Jan. 1, 1974 (dollars per short ton)
Sodium carbonate:	
Calcined (soda ash)	2.40
Hydrated and sesquicarbonate	4.00
Sodium sulfate:	
Crude (salt cake)	Free
Anhydrous	.40
Crystallized (Glauber's salt)	.80

Table 3.—U.S. exports of sodium carbonate and sodium sulfate
(Thousand short tons and thousand dollars)

Year	Sodium carbonate		Sodium sulfate	
	Quantity	Value	Quantity	Value
1972	480	18,911	29	926
1973	425	16,064	45	2,049
1974	564	34,156	51	3,250

Table 4.—U.S. imports for consumption of sodium sulfate
(Thousand short tons and thousand dollars)

Year	Crude (salt cake) [1]		Anhydrous		Total [1]	
	Quantity	Value	Quantity	Value	Quantity	Value
1972	226	4,082	73	1,275	299	5,357
1973	240	4,054	80	1,602	320	5,656
1974	277	7,162	98	3,220	375	10,382

[1] Includes Glauber's salt as follows: 1972, 56 tons ($1,491); 1973, 110 tons ($2,200); 1974, 1,270 tons ($29,166).

Table 5.—U.S. imports for consumption of sodium carbonate and bicarbonate in 1974
(Thousand short tons and thousand dollars)

	Quantity	Value
Soda ash	32	3,258
Sodium bicarbonate	3	331
Total	35	3,589

WORLD REVIEW

A perusal of tables 6 and 7, world data on production of soda ash and sodium sulfate, reveals that only 18% of the world's soda ash comes from natural sources, and the United States produced 94% of this quantity. Of the synthetic or Solvay soda ash, East Europe and U.S.S.R. produced 40%; Western European nations, 29% (69% for all Europe); North America, 20%; and Asia, 11%. The five top ranking soda ash producing nations of the world, in order, were as follows: The United States, U.S.S.R., France, West Germany, and Japan. Together they produced 72% of the world's soda ash.

Natural sodium sulfate provided 45% of the world's supply while the byproduct or synthetic salt cake provided 55%. The North American nations produced 72% of the natural sodium sulfate, but European nations supplied 50% of the synthetic product. The five top ranking sodium sulfate producing nations of the world, in order, were as follows: The United States, Canada, U.S.S.R., Japan, and West Germany. Together they produced 73% of the world's sodium sulfate.

Africa.—Outside the United States, the largest deposits of natural soda ash occurred in Africa as a series of alkaline lakes located in Kenya, Sudan, Chad, Botswana, and Tanzania. The Magadi Soda Co., a subsidiary of Imperial Chemical Industries Ltd. (ICI), of the United Kingdom produced about 220,000 tons of soda ash in 1974 from Lake Magadi, Kenya, the reserves of which were estimated to be over 100 million tons. There was also a commercial operation at Dongola in Sudan producing an estimated 50,000 tons per year from a natron deposit. Most of the output from both of these facilities was exported to other African, Asian, and Arabian countries.

The alkali deposits in Tanzania were being investigated by a consortium of Japanese companies considering the possibilities of commercial exploitation.[9]

Brazil.—At present the only soda ash producer in Brazil is Companhia Nacional de Alcalis (Alcanorte) with a plant at Cabo Frio in the State of Rio de Janeiro. The company revealed plans for the construction of a new plant at Macau, Rio Grande de Norte on the Atlantic coast close to an existing solar salt operation. The new plant is scheduled to have a capacity of 200,000 tons of soda ash per year and is due to be on-stream in 1977.[10]

Canada.—Canada was a major world producer of sodium sulfate at about 604,000 tons per year with over 90% of it coming from natural brine lakes in Saskatchewan and Alberta. Seven plants utilized the resources from these Western Provinces, the reserves of which were estimated at 100 millions tons. Canada exported about 30% of its natural sodium sulfate to the United States and consumed about 75% of the remainder in its pulp and paper industry.[11]

China, People's Republic of.—The alkaline deposits in Manchuria, People's Republic of China, were being worked, but nothing has been published regarding their production or potential. The total soda ash production from the People's Republic of China has been estimated at 1.65 million tons per year.[12]

Europe.—Increases in soda ash production capacity are planned at Varna, Bulgaria (additional 800,000 tons per year), and Torrelavega, Spain (additional 340,000 tons per year).[13]

Japan.—Japan was reported to have produced 1,500,000 short tons of synthetic soda ash and 475,000 short tons of byproduct sodium sulfate. The sodium sulfate was produced during the manufacture of rayon.

Mexico.—Mexico had a production capacity of about 200,000 short tons of sodium sulfate per year in 1974 with most of it consumed in the detergent and cellulose industries. A major sodium sulfate plant was located in Laguna del Rey, Coahuila. Soda ash production in Mexico was about 390,000 short tons in 1974.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Poland, Romania, and the United Kingdom are assumed to have produced manufactured sodium sulfate, and other unlisted countries may have produced this commodity, but production figures are not reported, and available general information is inadequate for the formulation of reliable estimates of output levels.

[2] Natural mine output, excluding byproduct output from the nitrate industry, which is reported under "Manufactured."

[3] Sold or used by producers.

[4] Conjectural estimates based on 1968 information on natural sodium sulfate only.

[5] Byproduct of nitrate industry.

[6] Quantities of manufactured sodium sulfate credited to Spain are reported in official sources in such a way as to indicate that they are in addition to the quantities reported as mined (reported in this table under "Natural") but some duplication may exist.

[7] Derived approximate figure; difference between reported total sodium sulfate production (natural and manufactured, undifferentiated) and reported quantity of natural sodium sulfate sold or used by producers.

TECHNOLOGY

A survey of energy requirements for production of sodium compounds was made in 1974. Average data for production of natural compounds are as follows: Soda ash from trona, 2,100 kilowatt-hours per ton; sodium sulfate from brine, 1,320 kilowatt-hours per ton.

Stone

By Harold J. Drake [1]

Total production of stone, dimension and crushed, decreased 2% from the 1.1-billion-ton output of 1973. Total value, however, increased 10% to a new high of $2.2 billion. Output of dimension stone, at 1.9 million tons valued at $100.3 million, was up 21% in quantity and 17% in value. Output of crushed stone declined 2% in quantity but rose 10% in value to 1.04 billion tons valued at $2.1 billion. Crushed stone accounted for nearly 100% of the quantity and 95% of the value of the stone production.

Production of dimension granite declined 8%, that of limestone and dolomite increased 40%, and that of sandstone, quartz, and quartzite declined 12%. Production of marble gained 52%, whereas slate recorded a decline of 10%. The principal types of crushed stone recorded both increases and decreases in production during the year. Production increases were reported for traprock, 15%, and sandstone, quartz, and quartzite, 2%. Limestone and dolomite decreased 3%, granite 2%, and shell, 8%.

Consumption of crushed stone in major end uses also showed mixed results during the year. Crushed stone used for calcium and lime decreased 5% and 10%, respectively; uses as flux stone and in agriculture increased 10% and 24%, respectively. The use of crushed stone in the remaining major end use, the manufacture of portland cement, was essentially unchanged.

Domestic producers of crushed stone, experiencing higher operating costs in 1974, reluctantly increased prices. The average unit value for crushed stone, f.o.b. quarry, rose $0.20 to $2 per ton. The average unit value for dimension stone declined $1.97 to $52.39 per ton. Exports of dimension stone rose sharply but still represented only a small part of domestic production. Imports of dimension stone rose 4% in value. Exports of crushed stone increased 11% in quantity and 23% in value.

Table 1.—Salient stone statistics in the United States [1]

(Thousand short tons and thousand dollars)

	1970	1971	1972	1973	1974

[2] Data do not add to totals shown because of independent rounding.

Legislation and Government Programs.—The U.S. International Trade Commission (formerly the U.S. Tariff Commission) instituted two investigations under section 301(c)(2) of the Trade Expansion Act of 1962 to determine whether, as a result in major part of concessions granted under trade agreements, articles like or directly competitive with manufactured granite are being imported into the United States in such increased quantities as to cause, or threaten to cause, the unemployment or underemployment of a significant number or proportion of the workers of two firms. The two firms, Joseph Weiss & Sons, Inc., Brooklyn, N.Y., and Johns Swenson Granite Co., Concord, N.H., filed separate petitions on behalf of their workers and former workers. "Investigations were continuing at yearend."

DIMENSION STONE

DOMESTIC PRODUCTION

Of the total quantity of dimension stone sold or used in 1974, granite accounted for 34%; limestone and dolomite, 27%; sandstone, quartz, and quartzite, 14%; slate, 4%; marble, 4%; and other stone, 17%. Output of dimension stone totaled 1.9 million tons valued at $100.3 million. Production of granite totaled 657,758 tons valued at $51.4 million, a tonnage level 8% below that of the preceding year. Limestone and dolomite were up 40% in tonnage to 516,621 tons valued at $18.2 million. Sandstone, quartz, and quartzite declined 12% to 260,936 tons valued at $8.7 million. Slate production declined 10% to 78,690 tons valued at $8.2 million. Marble production rose 52% to 73,455 tons valued at $11.7 million. Dimension stone was produced in 44 States, of which Georgia, Indiana, Ohio, Pennsylvania, and Vermont accounted for about half of the output.

CONSUMPTION AND USES

Apparent consumption of dimension stone, in terms of value, rose 12% to $140.0 million; however, tonnage was believed to have declined in 1974. The share of the market supplied by U.S. producers rose from 69% in 1973 to 72% in 1974.

The value of dimension granite consumed in 1974 rose 11% to $60.7 million. The value of the limestone and dolomite used rose 48% to $16.9 million while that of sandstone, quartz, and quartzite was $9.4 million. Consumption of marble was valued at $31.1 million with approximately 62% of the value represented by foreign marble.

Consumption of domestically produced rough dimension stone totaled 1.3 million tons valued at $32.7 million compared with 960,000 tons valued at $24.5 million in 1973. Use of domestically produced dressed stone was up 4% to 640,000 tons valued at $67.7 million. Cut stone, sawed stone, monumental stone, and house stone veneer accounted for much of the dressed stone, and each recorded gains in 1974. Consumption of cut stone totaled 129,000 tons valued at $21 million, sawed stone, 125,000 tons valued at $7.2 million, monumental stone, 47,000 tons valued at $16.5 million, and veneer, 94,000 tons valued at $4.6 million.

PRICES

Average values for dimension stone in 1974, as reported to the Bureau of Mines, were as follows, in dollars per ton:

	Building		Monumental, rough, dressed	Flagging, dressed
	Rough	Dressed		
Granite	$41.41	$147.35	$83.48	--
Marble	83.61	294.09	--	--
Limestone	17.44	59.36	--	$28.45
Sandstone	23.85	47.26	--	40.67
Slate	--	104.50	--	43.81
Miscellaneous	4.82	69.00	--	--

FOREIGN TRADE

U.S. exports of dimension stone were valued at $5.6 million in 1974 compared with $2.8 million in 1973. Most of the increased value for foreign shipments was accounted for by building and monumental dolomite and other processed stone. Canada, the United Kingdom, and Italy were the principal recipients.

U.S. imports of dimension stone rose 4% in value to $43.2 million. Marble, breccia, and onyx accounted for 45% of the value of imports, granite 22%, slate 18%, and travertine 8%. The remainder consisted of limestone, and undifferentiated stone. Imports of marble were up 5%, granite 8%, and slate 18% in value. Imports of marble slabs and paving tiles, the most important import item, decreased 5% in quantity, but increased 10% in value. Dressed travertine declined 21% in quantity but only 2% in value. Rough and dressed granite declined 39% in quantity and 26% in value.

The principal sources of most of the imported dimension stone were Italy and Portugal who supplied most of the marble and travertine and, along with Spain and the United Kingdom, most of the slate. Italy and Canada supplied most of the granite; the remainder was accounted for by numerous other countries.

TECHNOLOGY

A report to the National Science Foundation by Martin Marietta Corp., Baltimore, Md., and the National Crushed Stone Association, Washington, D.C., detailed the results of a study to determine the possibility of applying sophisticated space industry technology to the crushed stone industry.[2] The comprehensive study stated that the major technical challenges to the crushed stone industry were efficient blasting without detrimental effects, maximum utilization of products and resources, and improved equipment wear and maintenance. The study concluded that no mechanism currently existed for directly translating research results into innovations of practical value to quarry operators and suggested that this problem needed further study.

A new method for grinding stone and concrete using coated abrasive belts and high-horsepower, high-speed grinders was described.[3] The new method utilizes high speeds and dry-grinding conditions and may be of particular use to producers of concrete block. The use of diamond tools for stoneworking was reported in a number of studies. One report dealt with the development of a method and a tool for wire sawing hard stones with bonded abrasives.[4] Rock drilling and stone machining with diamond tools were discussed.[5] The use of diamond tools in all phases of stone processing was extensively covered.[6]

CRUSHED STONE

DOMESTIC PRODUCTION

Crushed stone production declined 2% in quantity but rose 10% in value to 1.04 billion tons valued at $2.1 billion. The decline in quantity was partly offset by the increased coverage of domestic producers. Production of limestone and dolomite declined 3% in quantity but rose 8% in value. Granite production declined 2% in quantity and increased 10% in value. Together, these two kinds of crushed stone accounted for 84% of the total quantity and 80% of the total value of crushed stone in 1974. Output of traprock rose 15% in quantity and 23% in value to 96.9 million tons valued at $217.9 million. Production of sandstone, quartz, and quartzite was up 2% to 31.1 million tons valued $77.8 million. Output of crushed shell declined 8% to 18.2 million tons valued at $43.6 million, and crushed marble output fell 17% to 1.7 million tons valued at $30.6 million.

Crushed stone was produced in every State except Delaware. Pennsylvania produced the most crushed stone, followed closely by Illinois, Texas, Florida, and Ohio, in that order. Limestone and dolomite were produced in 46 States led by Illinois, Pennsylvania, Texas, Florida, Ohio and Missouri. States leading in production of granite were Georgia, North Carolina, Virginia, and South Carolina. Traprock was produced primarily in Oregon, Washington, New Jersey, Connecticut, Massachusetts, and California. Sandstone, quartz, and quartzite were produced mainly in Pennsylvania, Arkansas, and California. Shell was produced almost entirely in Louisiana and Texas. Other kinds of stone were produced in many different States but mainly in California, Pennsylvania, Alaska and New Mexico.

Domestic producers were faced with numerous operating problems in addition to inflation, recession, and the energy crisis. Concern rose for protecting the environment from air, water, and noise pollution derived from quarrying operations. The principal problems were suppressing dust and treating process water, both of which were costly. Many producers found that zoning ordinances were being enacted that seriously reduced their stone resources and threatened their future operations.[7] Labor costs continued to rise but they appear to have been offset by increased productivity. Maintenance cost of heavy equipment, particularly crushers, rose rapidly in 1974.

The increased demand anticipated for the future has led to the erection of new plants and the modernization and expansion of others. Aggregate producers were advised to develop their managerial skills regarding capital investment programs.[8] Florida Rock Industries, Inc., Jacksonville, Fla., built a new plant at Fort Myers, Fla., with an hourly capacity of 350 tons which, by careful design, can be doubled by the addition of a few major pieces of equipment.[9] Georgia Marble Co. placed into operation a new crushed stone plant at Douglasville Ga.[10] Operated by Consolidated Quarries Division of the company, the plant is semimobile and can be expanded to 800 tons per hour. In order to supply crushed stone for the Gathright Lake Project in the George Washington National Forest, the Jarfo Co. of Salem, Va., erected a crushed stone plant that will be converted to a roadstone operation when the dam is completed.[11] Leesburg Stone Co., Leesburg, Va., demolished its old 150-ton-per-hour crushing plant near Leesburg and erected in its place an 800-ton-per-hour plant more capable of supplying expanding markets in Virginia and Washington, D.C.[12] The annual capacity of the new plant is 1.5 million tons, which can easily be increased to 2.5 million tons by adding a large-size tertiary crusher. Concern for the environment and neighborhood relations led New Haven Trap Rock/Tomasso, North Branford, Conn., to embark on a program of modernization to improve plant performance and to develop an effective environmental protection program.[13] After pollution control measures were put into effect, an open house was held to acquaint local residents with the work being done in the quarry and the measures undertaken by the company to control pollution. Prior to building its new crushed granite plant at Columbus, Ga., LBI Quarries, Inc., Rome, Ga., designed the operation to conform to all antipollution standards.[14] The Environmental Protection Division, Georgia Department of Natural Resources, directed the company to submit a reclamation and conservation plan for approval before beginning operations and for each year thereafter.

The versatility and usefulness of portable crushing and screening plants were described in detail.[15] Lecanto Corp., Lecanto, Fla., in its hard limestone quarry used tire-mounted screens, crushers, and conveyors.[16] The advantages of mobility included the ability to follow the quarry face and to easily change the equipment whenever necessary to produce a different product mix. Two portable screening and crushing plants were used by Bruening Rock Products Co., Decorah, Iowa, to service 26 quarries.[17] Consolidated Quarries Div., Georgia Marble Co., Litonia, Ga., used a semiportable plant to sharply increase productive capacity and to manufacture a wider range of aggregate sizes.[18] Semiportable equipment was used for similar purposes by Hoover, Inc., Loganville, Ga.[19] The equipment reportedly delivers a wide variety of products, has increased productivity, and can be quickly changed to meet changed customer specifications. In addition, Hoover, Inc., used semiportable crushing and screen equipment to custom-crush granite for other mineral companies in the area.[20] Colorado Lien Co., Fort Collins, Colo., used a new portable crushing plant in conjunction with an expanded fine-grinding plant to sharply increase its capability of supplying its market area.[21] The company also installed dust collection equipment in its fine-grinding plant. Portability was a prime concern of Becker Sand and Gravel Co., Cheraw, S.C., when it erected its new crushed granite plant near Jefferson, S.C.[22] Each of the plant's four processing sections were designed for a high degree of flexibility in arrangement in order to rapidly adjust to changing product demand.

CONSUMPTION AND USES

Apparent consumption in 1974 was equivalent to production inasmuch as imports and exports were about equal. Consumption was valued at $2.1 billion. The total 1.04 billion ton production comprised 72% limestone and dolomite, 11% granite, 9% traprock, 3% sandstone, quartz and quartzite, 2% shell, and 3% other kinds of crushed stone. Compared with 1973, consumption of limestone and dolomite was off 3% in quantity to 752 million tons valued at $1.4 billion. Crushed granite was down 2% to 118.6 million tons valued at $238.1 million, and traprock valued at $217.9 million, rose 15% to 96.9 million tons. Arenaceous stone, such as sandstone, was up 2% in quantity to 31.1 million tons valued at $77.8 million.

Construction aggregate continued to be the major use for crushed stone. In 1974, this use accounted for 68% of the total and amounted to 709.4 million tons valued at $1.4 billion. The three principal components of this type of use were dense-graded roadbase stone (off 6% to 245.6 million tons valued at $440.4 million), coarse concrete aggregate (off 11% to 139.3 million tons valued at $276.6 million), and unspecified construction aggregate (off 2% to 128.9 million tons valued at $264.0 million). Consumption of bituminous aggregate, another major construction use, was essentially unchanged at 102.8 million tons valued at $226 million. The main nonconstruction uses were agricultural stone (up 24%), cement manufacture (unchanged), lime manufacture (down 5%), and flux stone (up 10%).

PRICES

Quotations in Engineering News-Record for carload lots of ¾-inch and 1-½-inch crushed stone in 1974, exclusive of discounts, ranged from $6.75 per ton in Minneapolis to $1.75 per ton in Birmingham. The average price of ¾-inch crushed stone was $4.30 and that of 1-½-inch stone was $4.24 for 17 major cities. Prices per ton for industrial fillers and extenders, as reported in the American Paint Journal, were as follows, in dollars:

Silica, amorphous, ultrafine-ground	69.00
Silica, crystalline	20.50– 45.40
Whiting, precipitated surface-treated	48.00
Whiting, dry-ground, 325 mesh	16.00– 38.00
Whiting, precipitated, U.S.P	50.00–117.00
Whiting, precipitated, technical	33.00– 44.00
Whiting, natural, water-ground	34.00– 54.00

FOREIGN TRADE

Exports of crushed and broken stone totaled 3.4 million tons valued at $12.6 million. Exports increased 11% in quantity and 23% in value over the levels of the preceding year. Exports of crushed stone consisted almost entirely of granite, limestone, and other calcareous stone. The major increase in exports was accounted for by fluxing limestone, which accounted for 80% of all exports. As in past years, Canada was the principal market for exported crushed stone.

Imports of crushed stone totaled 3.5 million tons valued at $5.7 million and were about equally divided between limestone and other kinds of stone. In terms of quantity, imports were up 8%; in terms of value, up 14%. Canada was the principal source of crushed stone imports.

Imports of dry, ground whiting rose 28% in quantity and 87% in value to 34,181 tons valued at $1.6 million. Imports of precipitated chalk whiting were about the same as in 1973, but with a 36% increase in value.

WORLD REVIEW

Canada.—Production of limestone on Texada Island, British Columbia, is used principally in the manufacture of cement and lime. Four companies operated quarries on Texada and barged much of the output to Vancouver, British Columbia, and Washington State. Barge capacities ranged up to 20,000 tons and distances traveled up to 400 miles.

[22] Trauffer, W. E. Becker's New 250-tph Crushed Granite Plant. Pit & Quarry, v. 66, No. 11, 1974, pp. 64–66, 82, 92–93.

Panama.—The new crushed stone plant of Cantera Le Esmeralda, Ojo De Agua, Panama, reportedly was one of the most efficient and flexible operations in the Western hemisphere.[33] The company has begun producing specification material in large quantities, which should not only make the operation profitable, but also provide strong competition for other producers.

South Africa, Republic of.—Hippo Quarries Div., Hippo Holding Co. Ltd., operated an andesite quarry about 8 miles south of Johannesburg.[34] Output consists mainly of aggregate stone for building and road construction and top-quality crushed concrete sand. Stone reserves are sufficient for 50 years of production.

Sweden.—A. B. Mataki's stone quarry and crushing plant at Södra Sandby in southern Sweden has become a center of attraction because of its unusual layout and dust-free operation.[35] Swedish authorities stipulated that the operation of the quarry could continue only if it was absolutely dust-free. To achieve this requirement, the entire process line was completely sealed with openings only for stone feed and products delivery. A small vacuum is maintained within the line to insure that no dust escapes through the openings. Environmental safety is high and the noise level is low.

Other companies featuring dust-free operating conditions are Goteborgs Makadam A. B. at Göteborg on the west coast[36] and Armerad Betong near Listarum in the southern part of Sweden.[37] The Betong plant was the first erected since Sweden enacted laws requiring all rock-processing machinery to be closed.

United Kingdom.—Stavely Lime Products, Ltd., brought onstream a new crushing plant at its Doves Hole Quarry.[38] The plant, which replaced two other smaller plants, was needed not only to supply the expected increased long-term demand, but also to insure that current and future production could be achieved with maximum flexibility and economy. Tarmac Roadstone Holdings Ltd. continued exploitation of its gritstone-graywacke quarry near Shrewburg, Shropshire.[39] The company erected a new plant complete with extensive dust-control equipment and numerous trees to reduce the visual impact of the plant from local residents. Amey Roadstone Corporation Ltd., Britain's biggest producer of construction aggregates, uses a fleet of mobile diamond drilling rigs to evaluate the quality and quantity of its stone reserves. Using special coring equipment, the company, which normally produces over 33 million tons of aggregates per year, has improved its field efficiency and reduced its drilling costs.

TECHNOLOGY

Concern for the environment continued at a high level. The Federal Bureau of Mines published a study on dust control at crushed stone operations.[40] The study reported on the cost and efficiency of the fabric filter method, the wet suppression method, and a combination of the two methods. The three systems were being used by quarry operators. A fabric-type dust collection system was described.[41] The system is completely automatic and has the additional feature of modular construction, which easily permits increased capacity in the future by the addition of more modules. U.S. Lime Div. of The Flintkote Co., developed an effective dust control system at its Apex, Nev., stone quarry.[42] The company installed a water spray-wetting agent system at its crushing plant that was practically 100% effective, with the added benefits of cleaner working conditions and higher employee morale.

Automatic data processing was used in various ways by the crushed stone industry. One company used it to increase productivity by reducing manpower requirements.[33] Another company used the technique to monitor truck service and maintenance work in order to increase effective truck life.[34] Results of the program indicate that the optimum operating life of the equipment has been doubled. The height of the haul trucks is important in underground crushed stone mines. One company used 22-ton trucks with a loading height of 81 inches and equipped with articulated steering to haul rock to the primary crusher.[35] A significant study of cost-saving management techniques related to tires for off-highway equipment was conducted.[36] Production increases of 20% were obtained by the installation of air tools and positioning booms to reduce oversize and keep material flowing through the primary crusher.[37]

Quarry operators were provided with information regarding the effects of jointing and bedding on rock fragmentation when bench blasting.[38] The study also provided information on the use of inexpensive equipment and field techniques for mapping joints and bedding planes within the quarry. Recent results of studies on the sensitivity of various experimental explosive systems using ammonium nitrate as the oxidizing agent were published.[39] The safe use of fertilizer-grade ammonium nitrate as a blasting agent in crushed stone quarries was discussed.[40] The study reported on the physical properties, uses, hazards, and correct safety precautions. Water in quarry drill holes plagues operators. To overcome this problem, water gel cartridges were used.[41] When waterproof bags of ammonium nitrate proved unsatisfactory, dynamite or water gel was substituted. The final selection of the gel as the blasting agent was based on a higher degree of safety and preference by the workers in the quarry. On the other hand, dewatering of some blastholes is not only practical but there are economic benefits to be gained.[42]

Two potential markets were reported for stone. Wet-scrubbing of electric utility stack gases using lime, limestone, and other carbonate materials was discussed,[43] as was the basalt to form fibers for use as construction materials.[44]

The use of limestone to remove sulfur oxides from stack gases of electricity-generating plants was discussed.[45] If environmental pressure against open pit operations becomes too severe, it may become necessary to go underground for aggregate materials. Converting an open pit operation to an underground mine and the advantages in doing so were discussed.[46] Recycling waste aggregate products was a source of income for aggregate producers.[47]

W Withheld to avoid disclosing individual company confidential data.

[1] Includes rubble and irregular shaped stone.

[2] Includes a minor amount of unspecified rough stone for 1974.

[3] Includes data for dressed flagging, paving blocks, and unspecified dressed stone.

[4] Data may not add to totals shown because of independent rounding.

[5] Data include small amount of monumental stone (1974).

[6] Less than ½ unit.

[7] Includes data for flagging and monumental stone (1973).

[8] Data include flagging, uses not specified, and figure where symbol W appears for marble.

[9] Data include curbing, sawed stone, construction stone, and uses not specified.

[10] Includes small amount of slate used for house stone veneer.

[11] Data includes slate used for electrical purposes, and where symbol W appears for slate.

[12] Includes slate used for aquarium bottoms, building stone, fireplaces, monumental purposes (1974), and uses not specified.

[13] Produced by the following States in 1974, in order of value of output and with number of quarries: California (80), Virginia (4), New Jersey (1), Maryland (1), Pennsylvania (3), Hawaii (3), Oregon (20), New Mexico (2), and Washington (8).

[14] Data include sawed stone, house stone veneer, and flagging, 1973 data also include stone used for structural and sanitary purposes.

[15] Data include stone for paving blocks, and uses not specified; slate for aquarium bottoms, building stone, fireplaces, and monumental purposes (1974). 1973 data also include stone used for structural and sanitary purposes (excluding slate).

Table 5.—Granite (dimension stone) shipped or used by producers in the United States in 1974, by State

State	Active quarries	Quantity (short tons)	Value (thousands)
California	106	45,278	$946

[r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Produced by the following States in 1974 in order of tonnage: South Carolina, Mississippi, Texas, North Carolina, Michigan, Indiana, and Virginia.

[2] Includes marl used in agricultural limestone, agricultural marl and other soil conditioners, and nutrients.

[3] Data include stone used in dense-graded roadbase stone, unspecified aggregate, and fill.

[4] Data may not add to totals shown because of independent rounding.

[5] Includes stone used in terrazzo, cement manufacture, asphalt filler, roofing aggregates, chips, and granules, building products (1974), bedding material 1974, waste material (1973), uses not specified, and any data represented by the symbol W in granite.

[6] Includes agricultural limestone, other soil conditioners, and poultry grit and mineral food.

[7] Includes stone used for abrasives and mine dusting.

[8] Data include stone used in acid neutralization, building products, bedding material, disinfectant and animal sanitation, drain fields, paper manufacture, porcelain (1974), roofing aggregates, chips, and granules, stucco, waste material, magnesium metal manufacture (1973), use not specified, and any data represented by the symbol W in limestone and dolomite.

[9] Data combined to avoid disclosing confidential data. Includes unspecified aggregate, riprap and jetty stone, and manufactured fine aggregate. 1973 data include macadam aggregate, concrete aggregate, dense-graded roadbase stone, surface treatment and filter stone.

[10] Include agriculture limestone (1973) and poultry grit and mineral food.

[11] Includes roofing aggregates, chips, and granules, other uses not listed, bituminous aggregate (1973), and any data represented by the symbol W in marble.

[12] Includes ground sandstone, quartz, and quartzite.

[13] Includes stone used in poultry grit and mineral food, other filler, building products, drain fields, porcelain, roofing aggregates, chips and granules, waste material, uses not specified, and data represented by the symbol W in sandstone, quartz and quartzite.

[14] Includes stone used for bituminous aggregate, concrete aggregate, and surface treatment aggregate.

[15] Includes stone used for riprap and jetty stone, railroad ballast, asphalt filler (1973), and uses not specified.

[16] Data include stone used for poultry grit, asphalt filler, other fillers or extenders, bedding material, drain fields, roofing aggregates, chips, and granules, waste material, building products (1974), and uses not specified.

[17] Includes stone used for manufacture of fine aggregate, cement manufacture, abrasives, asphalt fillers, other fillers, drain fields, roofing aggregates, chips, and granules, filter stone (1974), building products (1974) bedding material (1974), waste material (1973), and uses not specified (1973).

[18] Data include stone used in acid neutralization, building products, chemicals, bedding material, drain fields, flour (slate), waste material, uses not listed in smaller quantities, and uses not specified.

Table 9.—Number and production of crushed-stone quarries in the United States, by size of operation

Sulfur and Pyrites

By Roland W. Merwin [1] and William F. Keyes [2]

There was a marked increase in sulfur prices in 1974 compared with those in 1973. The average net shipment value f.o.b. mine or plant for Frasch and recovered elemental sulfur, which accounted for 92% of the total shipments of sulfur in all forms in 1974, increased by 62% from $17.84 per long ton in 1973 to $28.88 per ton in 1974. There were corresponding increases in both export and import prices. Sulfur prices rose steadily during 1974; therefore, the average prices during 1974 did not fully reflect the substantially higher prices that prevailed at yearend. These higher prices resulted from a continuing substantial upsurge in sulfur demand for fertilizer manufacturing in both domestic and worldwide markets.

Production of sulfur in all forms in 1974 reached an alltime high, being 5% greater than in 1973. For the seventh consecutive year production continued to exceed apparent domestic consumption. Sulfur was produced by 68 companies at 178 operations in 31 States, but 10 companies with 56 operations accounted for 82% of the output. Production was concentrated in Texas and Louisiana. Together, these two States accounted for 83% of the total output. Distribution of production was Frasch sulfur 69%, recovered elemental sulfur 23%, and sulfur contained in other products 8%. There was a substantial increase in the production of both Frasch and recovered elemental sulfur over that of 1973, while the production of sulfur in other forms decreased slightly.

Shipments of sulfur in all forms to domestic and export markets reached an alltime high, being 5% more than those in 1973. The total value of shipments f.o.b. mine or plant was $337.1 million in 1974, compared with $207.8 million in 1973, an increase of 62%. Seventy-seven percent of the shipments were for domestic consumption and 23% for export. Shipments of sulfur in all forms in 1974 were 1% less than the quantity produced. As a result, producers' yearend stocks of Frasch and recovered elemental sulfur, after inventory adjustments, were slightly greater than at yearend 1973.

Apparent domestic consumption of sulfur in all forms reached an alltime high, 6% greater than that of 1973. Sulfur for domestic consumption came mainly from domestic sources: Frasch 49%, recovered elemental 23%, and sulfur in other forms 8%. The remaining 20% of the sulfur consumed was provided by imports of Frasch and recovered elemental sulfur.

The United States maintained its position as a substantial net exporter of sulfur in all forms for the fourth consecutive year. However, the quantity of net exports decreased by 19% compared with that in 1973. Exports of sulfur in all forms were 46% greater than in 1973 and were only 1% less than the alltime record exports in 1965. Imports of sulfur in all forms were at an alltime high, being 76% greater than in 1973. These high levels of exports and imports reflected substantial changes in trade patterns compared with those in 1973.

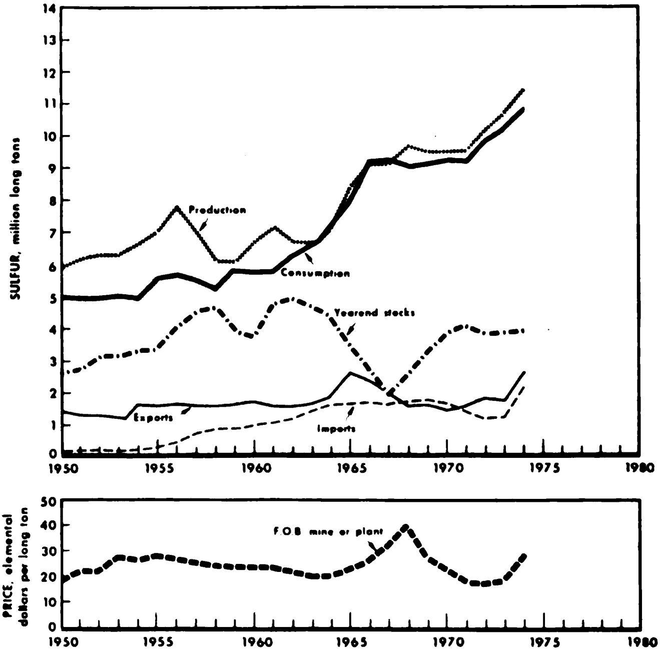

Figure 1.—Trends in the sulfur industry in the United States.

DOMESTIC PRODUCTION

Frasch Sulfur.—Frasch sulfur accounted for 69% of the domestic production of sulfur in all forms in 1974, compared with 70% in 1973. Production reached an alltime high in 1974, and was 4% greater than that of 1973. This record production was attained in the face of rapidly increasing operating costs, mainly in the form of higher natural gas prices. A mitigating factor was the substantially higher price level for Frasch sulfur.

In 1974, 12 Frasch mines produced sulfur. The producers and mines in Louisiana were Freeport Minerals Co. at Garden Island Bay, Grand Isle, Grande Ecaille, and Lake Pelto; and Texasgulf Inc., at Bully Camp. The producers and mines in Texas were Atlantic Richfield Co. at Fort Stockton; Duval Corp. at Rustler Springs; Jefferson Lake Sulphur Co. at Long Point Dome; and Texasgulf Inc., at Boling Dome, Fannett Dome, Moss Bluff Dome, and Spindletop Dome.

The 10 mines operated by Duval Corp., Freeport Minerals Co., and Texasgulf Inc., accounted for most of the Frasch production. Only a relatively small portion of the output was obtained from the other two producers operating one mine each.

Table 3.—Sulfur produced and shipped from Frasch mines in the United States
(Thousand long tons and thousand dollars)

Year	Production			Shipments	
	Texas	Louisiana	Total[1]	Quantity	Value[2]
1970	3,446	3,636	7,082	6,504	158,809
1971	3,408	3,616	7,025	6,738	117,894
1972	3,755	3,534	7,290	7,613	132,385
1973	4,294	3,311	7,605	7,438	138,578
1974	4,593	3,308	7,901	7,898	241,066

[1] Data may not add to totals shown because of independent rounding.
[2] F.o.b. mine.

There was a continuing tendency to concentrate production in the larger low-cost mines to counteract the adverse effect of increasing production costs. The five largest mines, with a production rate in excess of one-half million tons per year each, accounted for 81% of the total Frasch sulfur output, compared with 78% in 1973. They also accounted for 56% of the total production of sulfur in all forms during 1974, compared with 54% in 1973. Three medium-size mines, with production rates of more than 250,000 tons per year each, contributed an additional 11% of the year's Frasch production. The remaining 8% of the Frasch output came from four smaller mines.

Producers' shipments of Frasch sulfur were 6% more than those in 1973. This was a result of substantially greater shipments to export markets, as shipments to the domestic market decreased moderately. Approximately 33% of the total shipments were for export (24% in 1973), and 67% were for domestic consumption (76% in 1973). Total shipments were almost equal to production during 1974. However, because of inventory adjustments, producers' reported stocks at yearend 1974 were 2% less than at yearend 1973.

Because of an increase in shipments and the higher prices that prevailed, the total value of Frasch shipments, f.o.b. mine, increased by 74% over that of 1973. The average reported unit shipping value, f.o.b. mine, was $30.52 per long ton in 1974, compared with $18.63 per ton in 1973, an increase of 64%. This increase reflected the substantial improvements in sulfur prices throughout the year; however, these prices did not become fully effective until near yearend 1974.

Recovered Sulfur.—Recovered elemental sulfur accounted for 23% of the total domestic production of sulfur in all forms, compared with 22% in 1973. This reflected the rapidly increasing importance of recovered sulfur as a domestic supply source.

Production and shipments of recovered sulfur in 1974 reached alltime highs, with increases of 9% and 4% respectively over those of 1973. The total value of shipments in 1974 increased by 60% over that of 1973. The average reported industrywide shipment value f.o.b. plant was $23.79 per long ton in 1974, compared with $15.45 per ton in 1973, an increase of 54%. As a result of local competitive factors in the regional markets served by the recovered sulfur producers, including competition from Canadian sources in the northern tier of States, there were wide variations between the reported unit sales prices f.o.b. plant in the different regions of the Nation.

Recovered elemental sulfur production was nondiscretionary in that it was a byproduct from natural gas and petroleum refinery operations. It was produced by 53 companies at 134 plants in 28 States and at 1 plant in the Virgin Islands. Most of the plants were relatively small; only three reported an annual production exceeding 100,000 tons. The 10 largest plants accounted for 39% of the total output, and the combined production of the 5 leading States amounted to 70% of the total. By source, 54% was produced by 35 companies at 75 refineries or satellite plants treating refinery gases, and 46% was produced by 29 companies at 60 natural gas treatment plants.

The five largest recovered elemental sulfur producers were Exxon Co. U.S.A., Getty Oil Co., Gulf Oil Corp., Shell Oil Co., and Standard Oil Co. (Indiana). Together, their 40 plants accounted for 54% of recovered elemental sulfur production in 1974.

Texas and California were the leading recovered elemental sulfur producers, contributing 33% and 15% of the total 1974 output, respectively. Together, the contiguous States of Alabama, Florida, and Mississippi accounted for an additional 22% of the output, mainly from the treatment of dry sour natural gas and sour natural gas associated with petroleum in the deep Jurassic formations underlying these States. Production in this tristate area increased substantially over that of 1973, with indications of a further substantial increase in future years. Additionally, petroleum refineries, particularly those along the coastal areas of the Nation, expected to increase their recovered elemental sulfur production capabilities. It was anticipated that these actions would sharply increase production of recovered elemental sulfur within the next few years.

W Withheld to avoid disclosing individual company confidential data; included with "Other States."

[1] Includes Mississippi in 1973.

[2] Included with Louisiana in 1973.

[3] Combined to avoid disclosing individual company confidential data; includes Colorado, Delaware, Kansas (1973), Missouri, Montana, North Dakota, Oklahoma (1974), Utah, Virginia, Washington, and Virgin Islands.

[4] Data may not add to totals shown because of independent rounding.

Byproduct Sulfuric Acid.—The sulfur contained in byproduct sulfuric acid produced at copper, lead, and zinc roasters and smelters during 1974 amounted to 6% of the total domestic production of sulfur in all forms, compared with 5% in 1973. The total output was 9% more than in 1973, and the value of shipments was 21% more than in 1973. This output was produced by 12 companies at 22 plants in 13 States. Twelve acid plants operated in conjunction with copper smelters, and 10 plants operated as accessories to lead and zinc roasting and smelting operations. The five largest acid plants accounted for 49% of the output, and the combined production of five States amounted to 78% of the total.

The five largest producers of byproduct sulfuric acid were American Smelting and Refining Co., The Bunker Hill Co., Kennecott Copper Corp., Phelps Dodge Corp., and St. Joe Minerals Corp. Together, their 14 plants produced 73% of the output during 1974.

A number of additional byproduct sulfuric acid plants were either under construction in 1974 or in the planning stage. Current production was a relatively small proportion of the potential production at smelters, particularly at copper smelters. Additionally, existing environmental regulations required more effective sulfur oxide emission controls. With these conditions prevailing, it was anticipated that this type of sulfur production would increase rapidly during the next few years.

Table 6.—Byproduct sulfuric acid[1] (sulfuric content) produced in the United States
(Thousand long tons and thousand dollars)

Year	Copper plants[2]	Lead and zinc plants[3]	Total	Value
1970	218	318	[4] 537	23,744
1971	234	284	518	21,293
1972	295	251	546	22,897
1973	318	282	600	24,175
1974	373	281	654	29,370

[1] Includes acid from foreign materials.
[2] Excludes acid made from pyrites concentrates in Arizona, Montana, Tennessee, and Utah.
[3] Excludes acid made from native sulfur.
[4] Data do not add to total shown because of independent rounding.

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.—The sulfur contained in pyrites, hydrogen sulfide, and sulfur dioxide amounted to 2% of the total domestic production in all forms during 1974, compared with 3% in 1973. The total sulfur content in these products was 23% less than in 1973, and the shipment value of these combined products decreased 16% below that of 1973. These conditions reflected the decreasing importance of these products as a source of U.S. sulfur supply.

Pyrites was produced by three companies at three mines in three States, hydrogen sulfide by three companies at four plants in three States, and sulfur dioxide by two companies at two plants in two States. The three largest producers of these products were Cities Service Co. (pyrites, hydrogen sulfide, and sulfur dioxide), Phillips Petroleum Co. (hydrogen sulfide), and Shell Oil Co. (hydrogen sulfide). Together, their one mine and five plants accounted for 93% of the contained sulfur produced in the form of these products.

Table 7.—Pyrites, hydrogen sulfide, and sulfur dioxide sold or used in the United States
(Thousand long tons of sulfur content and thousand dollars)

Year	Pyrites	Hydrogen sulfide and sulfur dioxide	Total	Value

1971	316	126	442	9,530
1972	283	149	432	9,227
1973	212	88	600	7,188
1974	162	70	232	6,052

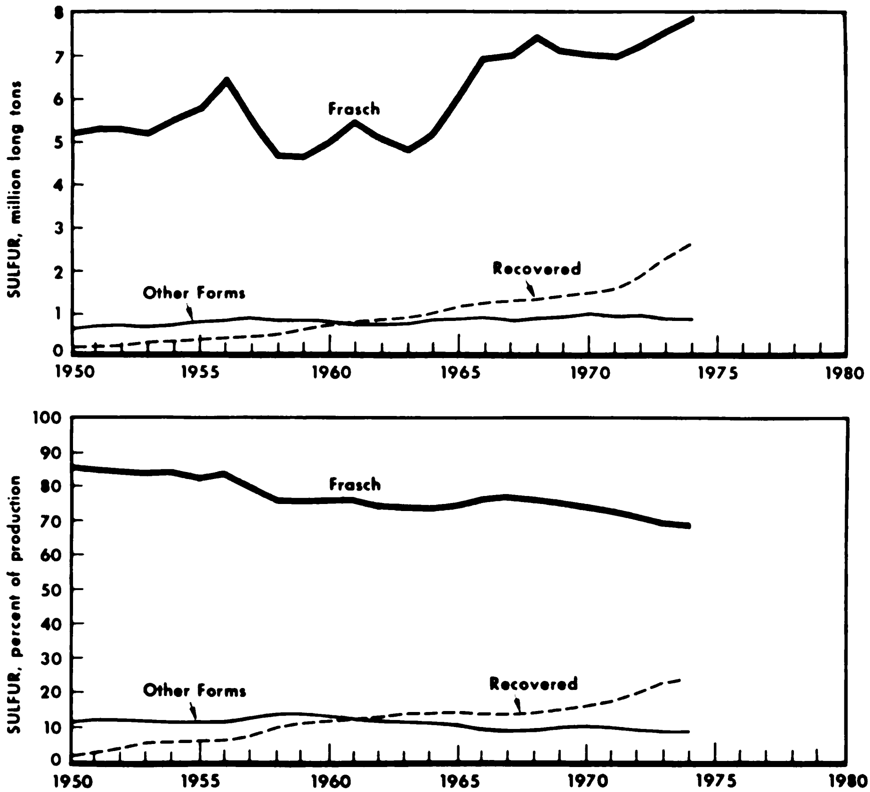

Figure 2.—Trends in the production of sulfur in the United States.

CONSUMPTION

Apparent domestic consumption of sulfur in all forms reached an alltime high in 1974, about 6% more than in 1973. This high level of consumption reflected a substantial improvement in demand by the domestic fertilizer industry, which was strong enough to offset a weakness in demand in the industrial sector. With many new phosphoric acid plants either coming into production, under construction, or in the planning stage, there were indications that domestic consumption would continue to improve during the next several years.

Eighty percent of the sulfur for domestic consumption was obtained from domestic sources, compared with 88% in 1973. The percentage distribution of supply sources was as follows: Domestic Frasch sulfur 49%, as compared with 55% in 1973; domestic recovered elemental sulfur 23%, compared with 24% in 1973; and combined domestic byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide 8%, compared with 9% in 1973. The remaining 20% of the sulfur was obtained from imports of Frasch and recovered elemental sulfur, compared with 12% in 1973.

Apparent sales of domestic Frasch sulfur to domestic consumers decreased by 365,000 tons, or 6% below those in 1973. Domestic producers of recovered elemental sulfur increased their apparent sales to domestic consumers by 96,000 tons, or 4% over those in 1973. The reported sale or use of byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide by domestic producers in domestic markets decreased by 14,000 tons, or 2% below those in 1973. Imports of Frasch and recovered elemental sulfur for domestic consumption increased by 928,000 long tons, or 76% above those in 1973. By source, imports from Mexico increased by 652,000 tons and those from Canada by 289,000 tons, while imports from other countries decreased by 13,000 tons.

Marketing strategies, logistic considerations, and price structures all contributed to the changes in consumption patterns by sources in 1974, compared with those in 1973. Available Frasch sulfur was channeled to higher priced world markets in which a strong demand existed, pending completion of domestic phosphoric acid plants to which forward commitments had been made. While Canadian imports of recovered elemental sulfur increased, their market penetration was limited by logistic considerations to the northern tier of States, a region that had only a limited market potential. Higher prices removed the restrictions on Mexican imports caused by antidumping duties. This factor, combined with a strong increase in demand in the southern States, allowed Mexico to resume its former position as a major supplier of Frasch sulfur to U.S. markets. As a result, supplies of domestic sulfur in all forms to the domestic market decreased by 283,000 tons below those of 1973. However, imported supplies of Frasch and recovered elemental sulfur increased by 928,000 tons, for a net increase in apparent domestic consumption of 645,000 tons.

Approximately 90% of all sulfur consumed was converted to sulfuric acid prior to eventual end use. The manufacture of fertilizers accounted for approximately 55% of all domestic sulfur consumption. Together, plastic and synthetic products, paper products, paints, nonferrous metal production, and explosives accounted for approximately 21% of domestic demand. The remaining 24% was used for a large number of relatively small individual end uses.

The approximate distribution of consumption was as follows: Southern States except Florida 42%; Florida 28%; North-Central States 11%; Western States 11%; and Northeastern States 8%.

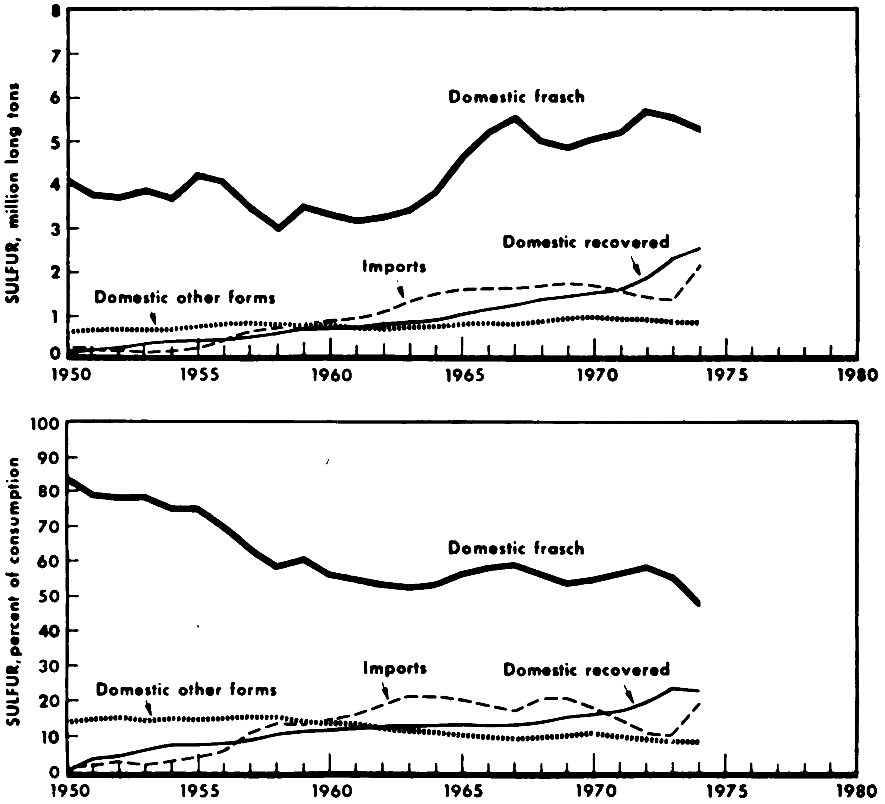

Figure 3.—Trends in the consumption of sulfur in the United States.

STOCKS

Yearend producers' stocks of combined Frasch and recovered elemental sulfur, after inventory adjustments, were 1% greater than at yearend 1973. There was a small decrease in Frasch stocks and a small increase in recovered elemental sulfur stocks. The combined yearend stocks amounted to approximately a 4.5-month supply based on the 1974 domestic and export demands for domestically produced Frasch and recovered elemental sulfur.

Table 9.—Producers' yearend stocks
(Thousand long tons)

Year	Frasch	Recovered	Total
1970	3,744	85	3,829
1971	4,023	97	4,120
1972	3,665	131	3,796
1973	3,816	111	3,927
1974	3,744	213	3,957

PRICES

Producers of Frasch and recovered elemental sulfur report annually on the value of their shipments, f.o.b. mine or plant. Such values vary widely between different mines or plants, depending upon prevailing selling prices in the markets they individually serve and the transportation costs to these markets.

The values f.o.b mine or plant do not necessarily reflect the ultimate selling prices because most sales of elemental sulfur, generally in the form of molten sulfur, are made ex-terminal near the points of consumption. Due to the highly competitive nature of the transactions, such prices are generally not made available.

Beginning in March 1974, and continuing through November 1974, major Frasch sulfur producers independently announced successive increases in the price of liquid sulfur ex-terminals. As a result of these increases, the quoted price of liquid sulfur ex-terminal, Tampa, Fla., the major U.S. marketing point, was $57 per long ton at yearend 1974, compared with $31 per ton at yearend 1973, an increase of 84%. There were similar price increases at other major marketing terminals.

These Frasch sulfur price increases were accepted by major consumers, particularly by the large fertilizer manufacturers in the Southeastern United States. It was recognized that Frasch sulfur production costs had increased to the point where certain low-cost Frasch mines could not continue to operate at the very low price levels that had prevailed for several years. It was also evident that a strong demand for sulfur in foreign markets created a condition in which the Frasch industry found it more profitable to sell in the export market than in the domestic market at the prices prevalent in early 1974. Additionally, the fertilizer manufacturing industry was expanding and required assured forward commitments of sulfur to supply large phosphoric acid plants that were under construction. It appeared to fertilizer manufacturers that the Frasch industry, with its large production capability, ample stocks, and well-established distribution facilities, offered the most assured source of supply for their expanding facilities. Finally, and this was a decisive factor, the high prices being obtained for finished fertilizers allowed the phosphate fertilizer manufacturers to pay substantially higher prices for sulfur.

However, because of the timing of the increases throughout the year and because of contractual agreements that further delayed their implementation, the higher price levels did not become fully effective until yearend 1974. As a result, the average sales value of shipments of Frasch sulfur f.o.b. mine for both domestic consumption and exports during 1974 rose to only $30.52 per long ton, compared with $18.63 per ton in 1973, an increase of $11.89 per ton, or 64%.

The recovered elemental sulfur industry was not able to obtain the full benefit of higher sulfur prices. This was because its marketing position was less favorable than that of the Frasch sulfur industry because it was subject to regional competitive factors and was more dependent upon sales to the industrial sector. Additionally, as recovered elemental sulfur is a nondiscretionary byproduct, there was a general tendency for the industry to sell in local markets at prices that were competitively lower than those of sulfur from other sources. Prices varied widely in different regions of the Nation as a result of these competitive factors. Overall, the reported unit shipment values f.o.b. plant in 1974 were $23.79 per ton, compared with $15.45 per ton in 1973, an increase of $8.34 per ton, or 54%.

Price increases for sulfur produced in other than the elemental form were considerably lower than those for elemental sulfur. This reflected the competitive positions prevailing in the limited regional markets for these products. As a result, the sales values, f.o.b. plant, of shipments of sulfur contained in byproduct sulfuric acid increased by only $4.62 per ton of contained sulfur, or 11% more than the prices prevailing during 1973. Similarly, the unit values, f.o.b. mine or plant, of sulfur contained in pyrites, hydrogen sulfide, and sulfur dioxide increased by only $2.13 per ton of contained sulfur, or 9% over that of 1973.

Table 10.—Reported sales values of shipments of elemental sulfur, f.o.b. mine or plant

(Dollars per long ton)

Year	Frasch	Recovered	Total
1970 --------	23.65	20.89	23.14
1971 --------	17.50	17.37	17.47
1972 --------	17.39	15.60	17.03
1973 --------	18.63	15.45	17.84
1974 --------	30.52	23.79	28.88

FOREIGN TRADE

The United States maintained its position as a net exporter of sulfur in 1974. However, net exports were substantially less than in 1973. Exports of sulfur in all forms in 1974 were 46% more than those in 1973, and imports of all forms were 76% more than those in 1973. As a result, total exports of sulfur exceeded total imports by only 451,000 long tons in 1974, compared with 554,000 tons in 1973, a decrease of 103,000 tons, or 19%.

The maintenance of the favorable export-import balance reflected the ability of the Frasch industry to expand its exports to a near alltime high in the face of heavy imports of Frasch and recovered sulfur that were at an alltime high. The Frasch industry, with its high production rate, ample stocks, and well-established export facilities, was able to channel its available sulfur to higher priced world export markets where a strong unsatisfied demand existed. This reflected the continued reliance in the world markets upon U.S. Frasch producers as an assured source of supply during a period in which logistic problems limited sulfur exports from Canada and production problems in Poland made that source of supply uncertain.

Higher prices in the U.S. market and logistic considerations combined to increase the imports of sulfur, moderately in the case of Canada and very strongly in the case of Mexico. Imports from Canada increased because of higher prices and the availability of additional transportation equipment that allowed Canadian sulfur to further penetrate the U.S. market in the northern tier of States. Higher prices for sulfur in the United States removed the restrictions on Mexican imports into their natural market in the southern area of the United States formerly imposed under the provisions of the Antidumping Act.

Exports were almost entirely in the form of Frasch sulfur. The tonnage of crude sulfur exported during 1974 was 46% greater than in 1973, and only 2% less than the previous alltime record exports in 1965. The total value of these exports increased by 178% over that of 1973. The average reported export value was $37.02 per ton in 1974, compared with $19.38 per ton in 1973, an increase of 91%. Together, Belgium and the Netherlands received 54% of these exports, mainly for transshipment to other European Community (EC) countries. Brazil, with 13%, was the third largest customer.

Following the pattern set in 1973, imports of sulfur in 1974 were entirely in the form of elemental sulfur. The total quantity of elemental sulfur imported in 1974 was 76% more than in 1973, and 20% greater than the previous alltime record imports of combined elemental sulfur and sulfur contained in pyrites in 1969. The total value of imports increased by 244% over that of 1973. The average declared customs value in 1974 was $23.78 per ton, compared with $12.17 per ton in 1973, an increase of 95%.

Imports of sulfur consisted largely of recovered sulfur from Canada and Frasch sulfur from Mexico. Imports from Canada reached an alltime high in 1974, being 32% greater than in 1973. Imports from Mexico were 216% greater than in 1973; 7% greater than the previous alltime peak imports in 1964; and 47% greater than the average imports during 1967–71, the period prior to the imposition of antidumping duties.

WORLD REVIEW

Reacting to a tight supply situation, sulfur prices rose rapidly throughout the world during 1974, reaching alltime highs by yearend. This tight supply position was primarily due to a continuing upsurge in sulfur demand for phosphatic fertilizer manufacturing which, combined with a projected still further higher demand in this sector, was of a magnitude that more than compensated for a weakness in demand for industrial uses of sulfur. Logistic problems which restricted the movement of sulfur from major producing areas with large producers' stocks, such as Canada, further contributed to this situation. Additionally, consumers reacted to rising prices and potential future shortages by increasing their stocks at points of consumption, particularly in northeast Europe and the Mediterranean region, and to a lesser extent in other consuming countries. However, at yearend 1974 there were indications that, as a result of an unexpected weakness in fertilizer demand and a continuing slackness in industrial consumption, there was a marked easing of demand for sulfur in world markets.[3] This condition continued into 1975 with the outlook for the future being uncertain.

Continuing the pattern prevalent during the past several years, world production of sulfur in all forms exceeded world demand by a substantial amount. This was reflected by an increase in producers' stocks of approximately 2.2 million long tons, with most of the increase being accounted for by a buildup in stocks of Canadian recovered elemental sulfur. Additionally, there was a substantial increase in Frasch sulfur stocks in Iraq. There were substantial increases in the production of Frasch sulfur, recovered elemental sulfur, and byproduct sulfuric acid compared with the previous year. However, the pyrites producing sector of the sulfur industry continued to face increasingly serious problems. Pyrites, particularly noncuprous pyrites, was becoming increasingly noncompetitive with elemental sulfur in the world markets, even at higher price levels for the elemental form.

Increasing attention was being given to the production of byproduct recovered elemental sulfur at refinery and natural gas plant operations in the Near East.[4] Nearly one-third of the world's reserves of sulfur recoverable at present price levels, using current technology, are located in this region. Most of the reserves are in the form of sulfur associated with sour petroleum and sour natural gas. If announced and prospective plans for large refinery installations, petrochemical complexes, and gas liquefaction plants materialize, the region could become one of the world's largest elemental sulfur producers.

While present plans propose that a substantial portion of the sulfur production would be utilized by local fertilizer plants, it is probable that most of the potential production would be exported to world markets in the form of elemental sulfur. Stabilization of political conditions in the Near East, with the assurance that the Suez Canal would remain open, would make this sulfur an attractive source of supply for Europe and North Africa.

The countries in the Near East, with their larger reserves of sulfur, and the countries in North Africa, with their large reserves of phosphate rock, all aspire to become large-scale manufacturers of finished phosphatic fertilizers for world markets. It has been proposed that an economical shipping arrangement that could meet the aspirations of both regions would be the shipping of bulk sulfur to North Africa and a backhaul of phosphate rock to the Persian Gulf.

The Caribbean area was also rapidly emerging as a major source of world elemental sulfur supply.[5] This was being brought about by the construction and expansion of large refineries treating sour crude petroleum for the production of low-sulfur residual fuel oils, with sulfur being recovered as a byproduct. There has been a tenfold increase in sulfur production capacity since 1968, with substantial additions in the construction and planning stages.

Shifting world trade patterns, the rapid development of new sources of elemental sulfur production, and environmental problems, such as the dusting associated with the shipment and storage of bulk, crushed crude sulfur have led many major producers to restudy their overseas transportation methods. Consumers prefer liquid sulfur deliveries. However, increasingly higher construction costs for the specialized liquid sulfur tank ships have mitigated against further expansion of this method of transport. The use of slate sulfur for bulk overseas shipments has partially alleviated the problem of dusting, but it has not been entirely effective in this respect. It has been proposed that pelletizing or prilling of elemental sulfur would provide a more satisfactory product for large-scale movement in international trade. Several relatively small plants for the production of pellets or prills have been built to evaluate these products from the standpoint of shipping characteristics, dusting problems, and consumer acceptance.

[5] Sulphur (London). Caribbean Recovered Sulphur Boom—Capacity Rapidly Approaching One Million Tons Per Year. No. 112, May/June 1974, pp. 35–44.

Canada.—The production of sulfur in all forms declined slightly from 8.0 million long tons in 1973 to 7.8 million tons in 1974. Recovered elemental sulfur produced at sour natural gas plants, refineries, and tar sand operations accounted for 91% of the output. The sulfur contained in byproduct sulfuric acid produced at nonferrous metal smelters accounted for essentially all of the remaining 9% of the output because there was only a negligible production of pyrites in 1974.

The Province of Alberta accounted for 87% of the Canadian output in 1974. All of the production was in the form of recovered elemental sulfur essentially from plants treating sour natural gas, with only a small fraction of the output being obtained at tar sand operations. Alberta's production of recovered elemental sulfur declined from an alltime peak of 7.0 million tons in 1973 to 6.8 million tons in 1974. Alberta's shipments of sulfur increased from 4.0 million tons in 1973 to 4.9 million tons in 1974. Of these shipments, 3.1 million tons was offshore shipments to foreign markets other than the United States, compared with 2.6 million tons in 1973. As in previous years, practically all of these offshore shipments were through the port of Vancouver, British Columbia. Mainly as a result of improvement in shipments, producers' stocks increased by only 1.9 million tons during 1974, compared with a 3.0 million ton increase in 1973; producers' stocks at yearend 1974 amounted to 13.5 million tons, compared with 11.6 million tons at yearend 1973. The value of marketed sulfur f.o.b. plant rose steadily throughout the year, increasing from $6.58 per long ton in December 1973 to $18.54 per ton in December 1974.[6] There were indications that, as old contracts expired, the value of a marketed sulfur would rise to about $25 per ton early in 1975.

Canadian analysts have concluded that Alberta production probably peaked in 1973 and that, in the absence of any new major sour natural gas discoveries, declining production curves already visible in several large fields will drop Alberta's sulfur production substantially by 1980. On the other hand, they also concluded that the next 5 years will probably be the longest term of sustained profitable marketing in the industry's history.[7]

The Province of Alberta's elemental sulfur producers continued their efforts to develop a more viable method for marketing their output. Working through the Sulphur Development Institute of Canada (SUDIC), an industry task force was working on the total logistic problem of moving Alberta's sulfur. They were reviewing all methods of forming, such as slating, prilling, and pelletizing, and studying the relative economics of all forms of transportation, including unit trains, pipelines, and liquid sulfur movements.[8]

The Province of Alberta Energy Resources Conservation Board estimated that the proved remaining recoverable reserves of sulfur from sour natural gas in the Province were approximately 168 million long tons at yearend 1974. It was also estimated that the proved remaining recoverable reserves of sulfur in the Athabasca tar sands amounted to 186 million tons and that the ultimate recoverable reserves of sulfur in crude bitumen in the Alberta tar sands would be about 1.7 billion tons.[9]

France.—Société Nationale des Pétroles d'Aquitaine, France's major recovered elemental sulfur producer, reported that it had discovered substantial new sour natural gas reserves in the Meillon field near the company's Lacq recovered sulfur complex in southwestern France.[10] This new discovery, at depths greater than 15,000 feet, should improve France's position as a major supplier of sulfur to the European market.

Germany, West.—The byproduct production of recovered elemental sulfur at sour natural gas treatment plants was being expanded rapidly. It was anticipated that production from this source would soon exceed 900,000 tons per year.[11]

Iran.—Iran has advanced more rapidly than other Near East countries in developing the production of recovered elemental sulfur at refineries and natural gas treatment plants. The production has been largely linked with the establishment of fertilizer, petrochemical, and natural gas liquefaction complexes. Plans have been announced for substantial expansions in these industries and for the building of large sulfur recovery units at existing and proposed petroleum refineries. This should lead to a rapid expansion of Iranian sulfur producton within the next decade.[12]

Iraq.—Expansion of facilities at the Mishraq Frasch sulfur mine increased its rated production capacity to 1 million tons per year. Owned and operated by the National Iraqi Minerals Co. (NIMCO), a wholly-owned Government company, this large mine is located near Mosul, about 250 miles north of Baghdad. Long recognized as containing one of the world's major Frasch sulfur deposits, the Mishraq mine and related shipping facilities were developed under the technical direction of Centrozap, the Polish mining engineering institute. NIMCO has been developing a marketing program, primarily export oriented, for both the Mishraq output and the substantial production of recovered elemental sulfur at Kirkuk, 150 miles north of Baghdad. Presently most of the output will be railed to the port of Umm Qasr on the Persian Gulf, about 550 miles south of Mishraq. There were also plans to link the Iraqi-Syrian railroad systems to provide a more direct outlet to the Mediterranean market.[13]

Japan.—The sulfur industry was faced with the problem of actual and potential oversupplies of sulfur in all forms. This has been brought about by the rapid expansion of recovered elemental sulfur production facilities at refineries and byproduct sulfuric acid production at nonferrous metal smelters. Recovered elemental sulfur production at refineries was greatly in excess of demand for this product. A cutback in refinery runs during the latter half of 1974 somewhat alleviated this problem. Additionally, some excess elemental sulfur was exported. The oversupply of byproduct sulfuric acid, which became evident in late 1974, led many nonferrous smelting companies to consider cutbacks in metal output to counteract the problem.

Mexico.—Continuing an upturn that began in 1973, conditions in the Frasch-based sulfur industry again improved substantially in 1974. This was primarily due to higher prices in world markets. Production increased from 1.6 million tons in 1973 to 2.3 million tons in 1974. Similarly exports increased from 0.8 million tons in 1973 to 1.9 million tons in 1974. Substantially larger shipments to the U.S. market accounted for approximately two-thirds of the increase in exports.

Poland.—Poland continued to improve its position as one of the major suppliers of sulfur to the European market. Production capacity was being increased, and emphasis was being placed on improving the marketing of sulfur. It was anticipated that the ongoing expansion of Poland's fleet of liquid sulfur tankers would reduce, and eventually eliminate, exports of crushed, dry, bulk sulfur. Additionally, Poland is expanding its sulfur-forming facilities so as to be able to increase its exports of prilled and pelletized sulfur.

Saudi Arabia.—With large proven reserves of sulfur associated with sour natural gas, Saudi Arabia was planning to become a major sulfur producer. It has been proposed to build a $4.5 billion gathering, sweetening, processing, and distribution project to handle 3.7 billion cubic feet per day of sour natural gas, most of which is presently flared. This project would produce approximately 3.5 million tons of recovered elemental sulfur per year.[14]

U.S.S.R.—While pyrites continued to maintain its position as one of the most substantial sources of sulfur production, there was an increasing degree of reliance upon the production of sulfur in other forms. Particular attention was being given to the production of recovered elemental sulfur as a byproduct at sour natural gas treatment plants. A new gas desulfurization plant was placed into operation at the Orenburg complex.[15] A third-stage expansion at the complex was planned, which would make it one of the largest single recovered elemental sulfur operations in the world, with an output of approximately 750,000 tons of sulfur per year. The production of native sulfur was to be increased by the development of a large Frasch sulfur mine with an initial capacity of 600,000 tons per year at the Yaborova complex in the sub-Carpathian region. Additionally, there were plans to increase the production of byproduct sulfuric acid at nonferrous smelter operations.

e Estimate. p Preliminary.

[1] The format of this table has been revised so as to include all recorded production of sulfur from mineral materials regardless of its origin or the form in which it is recovered. Thus, the sulfur content of pyrite, previously recorded in a separate table in this chapter, is included here (gross weight of pyrite is reported in table 16 of this chapter to continue the historical series). Similarly, for the first time the sulfur content of sulfuric acid produced directly from mineral materials other than pyrite without prior processing to elemental sulfur has been included where such data are available, or where a reasonable basis for estimation is available. Totals for each country have not been indicated as estimates even where all components of the total are estimates. The user is cautioned that any country total represents simply the summation of the detail for that country, including such estimates as may appear in the detail unless the total has been footnoted to the contrary. Because of the revisions in the format of this table, no figures have been indicated as being revised, although they may differ from figures appearing in tables 16 and/or 17 of the 1973 edition of this chapter.

[2] In addition to the countries listed, a number of nations refining oil and processing nonferrous metals may produce sulfur, but such output is regarded as small, and is largely if not entirely consumed by the producer.

[3] Detail has been estimated on the basis of a reported total for byproduct production.

[4] Detail has been estimated on the basis of a reported total for all sulfur.

[5] Exports, regarded as virtually equivalent to production, owing to minimal domestic consumption.

[6] Brazil and Egypt may also produce sulfur from metallurgical operations and/or from natural gas, but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[7] Chile, Czechoslovakia, and Pakistan may also produce sulfur from natural gas and/or petroleum, but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[8] Includes a small output from byproduct pyrite.

[9] Cyprus, Indonesia, and the Republic of Korea may also produce sulfur from petroleum refining, but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[10] Revised to zero.

[11] East Germany, North Korea, and Mexico may also produce sulfur from metallurgical operations but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[12] Less than ½ unit.

[13] Sulfur content of H_2S gas and liquid SO_2 not included elsewhere.

e Estimate. p Preliminary. r Revised.

[1] Data on sulfur content of pyrite, included in this table in previous editions of this chapter, have been reported with data on production of other forms of sulfur in table 15.

[2] In addition to the countries listed, Chile produces a small quantity of byproduct pyrite. The sulfur content of this pyrite is included in table 15 but no basis is available for determining the gross weight of this material.

[3] Sold or used by producers.

[4] Exports.

TECHNOLOGY

Sulfur technology advanced on several fronts during the year. Elemental sulfur recovery from new sources was investigated, new environmental problems were recognized, the controversy over stack gas scrubbing was narrowed down, and recovery of sulfur from coal came closer to realization. Additionally, basic research on sulfur and sulfur compounds was expanded, and new use applications were emerging from laboratories.

Future elemental sulfur supplies will come in part from sources not now contributing. One example was the continuing development of a process, by the College Park Metallurgy Research Center of the Bureau of Mines in Maryland, to smelt chalcopyrite in a manner in which all the sulfur is converted to the elemental form, thus eliminating stack gas emission of SO_2. The first and unique step in the process is to convert the chalcopyrite to a sulfur-deficient form by inert-atmosphere roasting. The iron is then leached before dissolving and electrowinning the copper. Elemental sulfur is recovered in both the roast and the leach steps.[16]

---

[16] U.S. Bureau of Mines. Mineral Research and Data Analysis Highlights. V. 1, No. 3, November 1974, p. 10.

Attention was diverted from the possible environmental effects of dilute SO_2 concentrations in the atmosphere to the problem of sulfates, as salts or as sulfuric acid, resulting from the oxidation of SO_2. The normal pH of rain in equilibrium with prevailing carbon dioxide concentrations is about 5.7. Much stronger acids have, however, been observed recently in the Northeastern United States, with pH values as low as 2.1 and averaging between 3 and 4. Records of pH are scarce prior to about 1963, but indications are that the pH was higher at that time. Nevertheless the sulfur content of rain and snow in New York State, as one example, has declined by 70% since 1950. This phenomenon of "acid rain" was attributed to lack of basic particulates in stack gas emissions, due principally to the use of cleaner fuels such as natural gas and oil but also to the removal of the particulates in gases from coal-fired boilers and furnaces. In two series of tests, it was reported that $SO_4{}^{2-}$ represented about 60% of the anions present in the acid rain, $NO_3{}^-$ about 22%, and Cl^- about 15%.[17] The phenomenon was considered all the more disturbing because it implicated the cleanest fuels in use today. Carried to its logical conclusion, it would require coal cleaning and conversion and stack gas scrubbing beyond what appear to be economic limits.

The acid rain problem was also perveived as a brake on use of tall stacks and intermittent emission controls. The Environmental Protection Agency (EPA) contended in numerous actions that a positive reduction of sulfur oxide emissions must be achieved, and that mere maintenance of ambient air quality does not meet the spirit of the Clean Air Act. The Tennessee Valley Authority (TVA), on the other hand, continued with plans to attain compliance with ambient SO_2 standards by intermittent controls (switching fuels or curtailing power production to maintain air quality) and the use of tall stacks. Following a decision in 1973, TVA continued with plans to extend the intermittent control-tall stack solution to 9 of its 12 coal-fired generating stations; the 3 remaining stations will meet ambient standards without further control by 1975.[18]

Sulfate emissions from automobiles were also credited with a contribution to atmospheric pollution. Evidence was found that the catalytic converters attached to automobile exhaust systems oxidize sulfur dioxide to sulfates, as well as performing their primary function of oxidizing hydrocarbon emissions. The EPA was to study the specific sulfate species emitted and their relationship to health, especially on a localized basis. Additional desulfurization by hydrotreating catalytic feedstock to refineries was to be studied.[19]

By yearend 1974, 20 stack gas scrubbers, chiefly using lime-limestone technology, had been built, and 15 more were under construction. Nevertheless, litigation continued to cloud future developments.

The Pennsylvania Commonwealth Court upheld a lower court opinion that emission control technology was not commercially available for the removal of sulfur oxides from stack gases of electrical generating plants.[20]

In a case brought in 1974 by Commonwealth Edison of Illinois against the Illinois Pollution Control Board, a State appellate court, early in 1975, ruled that data presented so far by the Control Board failed to establish either the technological or economic feasibility of sulfur removal from stack gases by the five technologies cited by the Board: Dry limestone injection, wet lime scrubbing, magnesium oxide scrubbing, catalytic conversion of SO_2 to SO_3, and fuel desulfurization. The fine levied by the Control Board was set aside by the Court.[21]

Prospects for compliance with provisions of the Clean Air Act of 1970 by electric utilities were diminished by differences of opinion between the utilities and EPA. The Clean Air Act required compliance by June 1975 with State plans implementing a national primary ambient air quality standard. In June 1974, EPA served violation notices with possible penalties on the Central Illinois Light Co. This was called the beginning of a "major effort" to force compliance with emissions standards. The EPA later proposed regulations allowing a State to designate areas in three classifications: (1) No significant increase in air pollution required, (2) moderate degradation permitted, and (3) pollution allowed to rise to national standard.[22] Power companies, led by the American Electric Power Co., Inc., alleged in numerous public statements that stack gas scrubbing has not been proved effective, reliable, or justifiable, and would create a sludge disposal problem of large proportions.

[21] Chemical Engineering. V. 82, No. 2, Jan. 20, 1975, pp. 42–43.

The Bureau of Mines issued a study of the sludge disposal problem. It was concluded that electric power industry adoption of lime or limestone postcombustion desulfurization systems may create a solid waste disposal problem and possibly contribute to water pollution. The estimated lime or limestone desulfurization capacity in 1980 of 86,000 megawatts, operating for 20 years, will generate enough solid waste (50% solids) to cover about 58 square miles to a depth of 20 feet. Toxic elements originating in the lime or limestone, coal, or fly ash may accumulate in the sluice water in a closed-loop operation. The magnesium present in dolomitic limestone might render it unusable because the magnesium sulfate formed is very soluble.[23] Such considerations indicated that either a use should be found for the sludge, as in roadbuilding or construction, or alternative processes that produce a less bulky, more easily handled, and more valuable product should be considered. The chief processes answering to this description are those that yield elemental sulfur from stack gas scrubbing.

The solubility of certain sludge constituents and the difficulty of consolidating the sludge were expected to be alleviated to a great extent at the new Bruce Mansfield power station at Shippingport, Pa. The pH of the slurry will be raised to about 11 with slaked lime, and a special additive, known as Calcilox, will be added. The sludge is expected to harden at the disposal dam to a material that will support a weight of 4.5 tons per square foot.[24]

Phase 1 of the pilot program to test the Bureau of Mines citrate process, which yields elemental sulfur as a final product, was put into operation at the Bunker Hill smelter in Kellogg, Idaho, in February 1974. This phase included only absorption of the sulfur oxides of the stack gases in the citrate solution and precipitation of elemental sulfur by injection of hydrogen sulfide into the solution. Several extended periods of successful operation were achieved during the year. Phase 2, the gas cooling and cleaning section that precedes the citrate section, and phase 3, the section to generate hydrogen sulfide from the elemental sulfur product and a fuel, such as natural gas, were due to be constructed and operating early in 1975. In laboratory investigations it was found that glycolate solutions may be advantageously substituted for citrate solutions. A further advance was the discovery that the elemental sulfur product could be floated with fine bubbles of injected air, without the necessity to add kerosine as a collector; this would improve the quality of the sulfur product and effect a cost saving.[25]

An announcement of the Bureau plan for demonstrating the citrate process at coal- or oil-fired steam-generating facilities equivalent to 30- to 60-watt generating capacity was made on August 12, 1974, in the Commerce Business Daily. A Request for Proposal (RFP) was issued on November 8, 1974. Proposals in response were received early in 1975 and were to be evaluated.[26] In a later development, emphasis was to be placed on coal-fired facilities.

The developing energy crisis focused attention on coal as the only available fuel to replace dwindling supplies of petroleum and natural gas; there was a unanimous opinion among technologists that nuclear, solar, geothermal, and oil shale energy would contribute only small increases to the Nation's energy supply by 1985. The problem of utilizing coal in an environmentally acceptable manner was very largely one of sulfur control and removal to maintain and improve air quality. A place was seen for numerous competing technologies to attain this objective, depending on local conditions at the point of energy delivery; besides stack gas scrubbing, other technologies, including coal cleaning by physical or chemical means and conversion of coal to clean (sulfur and ash free) gaseous, liquid, and solid fuels, were the object of intense and broad research. Many of these processes produced sulfur in reduced forms.

[26] Page 68 of work cited in footnote 25.

The Office of Coal Research of the U.S. Department of the Interior, with a greatly increased budget, accelerated its sponsoring of work in all areas of coal conversion technology and clean direct combustion.[37] A number of large industrial firms also devoted increased funds to efforts to desulfurize coal.

The pilot plant at Ft. Lewis, Wash., to demonstrate the solvent refining of coal (SRC) was started in October 1974, after being held up by delays in construction, and full operation was expected early in 1975. The process, in which coal is dissolved in a process-derived heavy aromatic solvent, yields a solid product, after filtering and solvent removal, containing 0.8% sulfur; all the inorganic and 60% to 70% of the organic sulfur is removed. A study was being prepared for publication under an interagency agreement with the EPA on aspects of sulfur and nitrogen removal from the SRC product.

A pilot-scale multicell fluidized-bed boiler (MFB) was operated by Pope, Evans, & Robbins Inc., in Alexandria, Va. The MFB uses a fluidized bed of calcium oxide added in the form of limestone or dolomite. A unit is being designed as a 30-megawatt module for boilers in the 60- to 800-megawatt range. Sulfur in the pulverized coal feed is retained in the bed during combustion, and a portion of the bed is continuously withdrawn; studies are underway to regenerate the calcium sulfate formed in the bed to yield CaO for recycle and SO_2 that can be used to make sulfuric acid. Tests showed that 90% of the sulfur in a ton of 4.1% sulfur coal can be removed by 550 pounds of low-quality limestone, with 48 pounds of common salt as a catalyst. Field erection of a 30-megawatt unit was started at the plant of the Monongahela Power Company at Rivesville, W. Va. It was claimed that annualized costs of such a boiler would be 35% below those of limestone scrubbers on the stack gas, and overall operating efficiency of the powerplant would be 39%, compared with approximately 35% for the stack gas cleanup route.

A major step in ultimate production of clean fuels from coal was taken by the Office of Coal Research when it released, on June 23, 1974, an RFP for a demonstration plant to produce clean boiler fuel from coal. Three proposals were received in 1974, and early in 1975 it was announced that the Coalcon Co. of New York had been awarded a contract for a plant to process 2,600 tons per day by pyrolysis in the presence of hydrogen at modest total pressure. Both liquid and gaseous products were to be produced, as well as a char that can be used to generate hydrogen. The plant was to be designed to operate mainly on high-sulfur eastern bituminous coal, and will produce substantial quantities of elemental sulfur.

In the search for an effective and economic solution to the apparent SO_2 emission dilemma, namely that the cost of effective, reliable control systems may ultimately prove very high although there is no dispute over the necessity to control local emissions, a number of processes that promise cost reductions were advanced during the year. Two systems for removing sulfur from coal were included. Battelle Memorial Institute tested an alkaline leach of finely ground coal, which it was said would remove 99% of the pyritic sulfur and up to 70% of the organic sulfur, largely as elemental sulfur. Kennecott Copper Corp.'s Ledgemont Laboratory also was successful in experimental work on oxidizing the pyritic sulfur in coal with oxygen. Both the Battelle and the Kennecott processes were stated to be effective under moderate conditions of temperature and pressure. It appeared at yearend that removal of much of the sulfur from coal by chemical, or even by physical, means might be accomplished without dissolving the coal, and the resulting fuel, if used in connection with tall stacks, might meet environmental standards. The relationship of this possibility to the new-found problem of acid rain, which it would not alleviate but which the Clean Air Act does not consider, remained for future investigation.

Research programs, designed not only to develop new uses for sulfur but to investigate its basic properties, were expanded in 1974. These projects were sponsored by Government agencies, trade organizations, sulfur producing companies, unversities, and independent laboratories. They were originally initiated because of a continuing oversupply of sulfur that lowered sulfur prices to a critical level for the sulfur producing industries. Additionally, it was anticipated that stricter enforcement of environmental regulations would lead to a rapid upsurge in the production of byproduct sulfur at environmental-related source points, with a further worsening of the oversupply and price positions. While the original intent of the research was to alleviate these situations, it became apparent as investigations continued that many of the proposed new uses showed promise of being of inherent value, independent of such considerations.

---

[37] U.S. Office of Coal Research. Shaping Coal's Future Through Technology. Annual Report 1974–75, 243 pp.

The American Chemical Society sponsored a symposium on April 2–3, 1974, for the purpose of reviewing the major research advances in the field of new sulfur uses. Fourteen published presentations covered plasticization of sulfur, sulfur-coated urea, sulfur coatings, sulfur in structural and construction materials, sulfur-asphalt pavements, sulfur-asphalt binders for roads, civil engineering applications of sulfur-based materials, cold region testing of sulfur foams and coatings, polyphenylene sulfide, lithium-sulfur cells, metal sulfide electrodes for secondary lithium batteries, and sodium-sulfur batteries.[28]

Academic research on the basic chemistry of sulfur and sulfur compounds was expanded in 1974. In depth studies of this type were being carried on by investigators at 363 universities and technical institutes in 40 countries.[29]

The Bureau of Mines continued its broadly based sulfur utilization research program. One segment of research covered the use of sulfur in coatings and structural materials.[30] Another phase of research investigated the use of sulfur as a construction material.[31] A third sector of the research was concerned with the use of sulfur for pollution abatement.[32] A major portion of the Bureau's research program was devoted to an investigation of the beneficial use of sulfur in sulfur-asphalt pavements. A substantial part of this particular research was conducted by the Texas A & M Research Foundation under a contract that was jointly funded by the Bureau of Mines and The Sulphur Institute.[33]

The Sulphur Development Institute of Canada continued to sponsor large-scale research programs designed to develop new uses for sulfur. Major phases of research included the development of sulfur foams as an insulating material under highways in cold climates, sulfur-asphalt compositions for highway pavement, and sulfur concretes for construction purposes. Financing was being provided by the Federal Government of Canada, the Provincial Government of Alberta, and recovered sulfur producers in Alberta.

An area of sulfur research that has shown a considerable promise of success has been the substitution of sulfur for a substantial portion of the asphalt in conventional asphaltic pavements. A number of investigators in the United States, Canada, and France have been independently pursuing this line of research. Their efforts have been largely prompted by an increasing shortage of asphalt and a rapid escalation in the cost of this product. It was estimated that annual savings of 10 to 26 million barrels of petroleum could be achieved in the United States through the partial substitution of sulfur for asphalt in road construction projects.[34] Additionally, research in progress has indicated a possible improvement in pavement characteristics.

Another promising major new use for sulfur was as an essential plant nutrient. Investigations have indicated that the amount of sulfur added to crops in the form of fertilizers was insufficient to meet the requirement for this element. It was estimated that the U.S. requirement was 2.5 to 4.0 million tons per year, whereas only about 1.0 million tons was actually being applied as a fertilizer ingredient.[35]

Use of sulfur in new energy sources was foreshadowed by development of the Solchem process by the Naval Research Laboratory, Washington, D.C. Reversible endothermic-exothermic reactions involving SO_3 and SO_2 are utilized to absorb heat in a solar reaction and deliver it to a heat exchanger.[36]

Talc, Soapstone and Pyrophyllite

By J. Robert Wells [1]

Demand for the various types of industrial talc continued strong in 1974, and producers mostly operated at or near capacity throughout the year.

International Talc Co., Inc., prominent in the list of U.S. producers for more than 75 years, sold in May 1974, its mining and processing facilities in St. Lawrence County, N.Y. to R. T. Vanderbilt Co., Inc. (formerly of New York City, recently relocated in Norwalk, Conn.). Operation of the transferred properties is being continued by Vanderbilt's subsidiary, Gouverneur Talc Company, Inc., the other major producer in that same area.

One of the largest talc producers in the United States, the United Sierra Division of Cyprus Mines Corp., recorded a number of notable changes in 1974. The firm name was changed to Cyprus Industrial Minerals Co.; the headquarters office was transferred from Trenton, N.J., to Los Angeles, Calif.; and a $2.2-million expansion of the company's talc grinding facilities at Three Forks, Gallatin County, Mont., was undertaken to make it possible to increase by 50% the output from the Yellowstone mine in adjacent Madison County.

American Lava Corp., a subsidiary of Minnesota Mining & Manufacturing Co. (3M Company) and long established as a prominent maker of steatite ceramics, was reorganized in 1974 to form one completely new division, Technical Ceramic Products, and part of a second, the Electronic Products department, both to be listed as units of 3M's Electrical Products group. It was announced that the facilities of the former American Lava Corp., in both Chattanooga, Tenn. and Laurens, S.C., will be operated without interruption by the new Technical Ceramic Products division to continue Lava's manufacturing of specialty ceramics.

Although the compositional and genetic relationships between talc and some of the minerals generally classified as asbestos continued to be cited by some writers in 1974 to raise questions concerning talc's possible complicity in human gastric and pulmonary disorders, there was no decisive evidence for concluding that there had been any material restriction of talc production and consumption on that account.

Talc was explicitly excluded from consideration in a clarifying revision interpreting the provisions of emission standards issued by the Environmental Protection Agency for asbestos, beryllium, and mercury. The statement was made that ". . . talc mines were not covered by the proposed standards; this was also intended to indicate that manufacturing operations that use talc or other materials contaminated with asbestos were not covered by the asbestos standard. In addition, the information available to the Agency at the time of promulgation (April 6, 1973) did not demonstrate that the mining and milling of such substances were major sources of asbestos emissions." It was further stated that "The Department of the Interior and the Department of Health, Education, and Welfare are studying the health effects of asbestos in talc." [2]

Legislation and Government Programs.—Defense materials inventories of the General Services Administration showed that Government holdings as of December 31, 1974, included 1,149 short tons of talc (steatite, block or lump) purchased in compliance with a stockpile objective, and 2,916 short tons of talc (steatite, ground) acquired in nonstockpile transactions.

Geological Survey, offered to grant loans of up to 50% of approved exploration costs for eligible deposits of block steatite talc, but no loans for that purpose were made in 1974. The allowable depletion rates for talc, established by the Tax Reform Act of 1969 and unchanged through 1974, were 22% on production of block steatite talc of domestic origin and 14% on foreign production of the same material; the same rate applied also to production of all other classes of talc from all sources.

[1] Excludes powders—talcum (in package), face, and compact.

A report was issued early in 1974 in which were published the papers presented at the conference on industrial hygiene of talc that was sponsored by the U.S. Department of the Interior in 1973.[3] A subsequent communication, dated December 4, 1974, and addressed to recipients of that report, contained the following statement:

"There is an erratum in the presentation by Dr. Schepers on page 69. The last sentence of the first full paragraph on this page should read:

> "Excess prevalence of lung cancer, which could not equally reasonably have been accounted for in terms of exposure to cigarette smoke, urban pollution or to prior, concurrent, or sequential exposure to true asbestos, has *never* been convincingly recorded."

The word "never" had been omitted in the original printing, completely reversing the intended significance of the passage.

DOMESTIC PRODUCTION

Mine production of crude talc and related minerals in the United States established new records in 1974 in both tonnage and total value, topping by 2% and 21%, respectively, the previous highs reached in 1973.

Talc-group minerals were produced from a total of 53 mines distributed throughout 14 States. Talc or soapstone was mined at one or more locations in each of those States; domestic production of pyrophyllite was limited, as in 1973, to the output of just five mines, all in North Carolina. The six leaders among the talc-group producing States (New York, Montana, Vermont, Texas, California, and North Carolina, ranked in descending order by tonnage—Vermont, Montana, New York, California, Texas, and North Carolina, ranked by value) jointly supplied 96% of the 1974 total domestic output. New York, the foremost producing State throughout most of the industry's history, remained in first place with regard to total production, but slipped in 1974 to third place in terms of value.

The 10 largest domestic producers of talc-minerals in 1974, listed alphabetically, were Cyprus Industrial Minerals Co., with mines in California, Montana, and Texas; Eastern Magnesia Talc Co. in Vermont; Johns-Manville Corp. (successor to L. Grantham Corp.) in California; Pfizer Inc., Minerals, Pigments & Metals Div. in California and Montana; Piedmont Minerals Co., Inc in North Carolina; Southern Clay Products, Inc., in Texas; R. T. Vanderbilt Co., Inc., in California, New York, and North Carolina; Westex Talc Co. in Texas; and Windsor Minerals, Inc., in Vermont. Those firms supplied 90% of the 1974 tonnage (93% of the total value), and the combined output of about 21 smaller producers made up the remainder.

---

[3] Goodwin, A. (comp. by). Proceedings of the Symposium on Talc, Washington, D.C., May 8, 1973. BuMines IC 8639, 1974, 102 pp.

Talc minerals were ground for sale or industrial use in 1974 at 35 mills operated by 29 companies in 11 States. Talc or soapstone mined in Nevada and Washington was shipped to other States for grinding, and talc from outside sources was ground in Nebraska, where there was no mine production.

Noteworthy among 1974 events in the talc industry were the continuing major expansions, especially of ultrafine-grinding facilities, on the part of several important producers in the western United States.

Table 2.—Talc, soapstone, and pyrophyllite produced in the United States, by State

State	1973 Quantity (short tons)	1973 Value (thousands)	1974 Quantity (short tons)	1974 Value (thousands)

[1] Data do not add to total shown because of independent rounding.

CONSUMPTION AND USES

Apparent domestic consumption of crude and ground talc, soapstone, and pyrophyllite (total sales plus imports minus exports) declined 11% to 911,000 tons from the first 1 million tons per year recorded in 1973. Reported 1974 sales of ground material were 11% less in tonnage than in 1973, but the average unit value increased $3.58, and the total value was unchanged from that of 1973. Approximately 21% of the total quantity of talc-group minerals sold or used by domestic producers in 1974 were consumed in the manufacture of ceramics, 15% was used in paint, and another 17% was exported.

The 1974 end-use distribution showed

an 11% increase in talc utilized for papermaking. This usage accounted for 8% of the total in 1974, compared with 5% and 7% in each of the 2 preceding years. It is no doubt significant in this regard that a number of talc processors in the western United States were pushing up their capacity to supply the ultrafine grades of material especially required by pulp and paper manufacturers for pitch control.

Table 4.—Pyrophyllite produced and sold by producers in the United States

STOCKS

According to estimates based on data reported by producers, the total quantity of crude, ground, and partly processed talc on hand in the United States (that is, mined but not yet sold or used) was approximately 225,000 tons on December 31, 1974, compared with 157,000 tons on that date in 1973.

PRICES

Engineering and Mining Journal, December 1974, quoted prices for domestic ground talc in carload lots, f.o.b. mine or mill, containers included, per short ton, as follows:

Vermont:	
98% through 325 mesh, bulk	$23.00
99.99% through 325 mesh, bags:	
Dry processed	67.00
Water beneficiated	92.00
New York:	
96% through 200 mesh	$31.00–32.00
99.9% through 325 mesh	40.00–50.00
100% through 325 mesh, fluid-energy ground	50.00–90.00
California:	
Standard	58.50
Fractionated	37.00–71.00
Micronized	62.00–104.00
Cosmetic-steatite	44.00–65.00
Georgia:	
98% through 200 mesh	14.00
99% through 325 mesh	25.00
100% through 325 mesh, fluid-energy ground	75.00

American Paint & Coatings Journal, December 30, 1974, listed the following prices per ton for paint-grade talcs in carload lots:

California:	
325 mesh, bags, mill:	
Fibrous, white, high oil absorption	$34.00–$37.00
Semifibrous, medium oil absorption	32.00–73.95
Montana:	
Ultrafine grind, f.o.b. mill	70.00
New York:	
Fibrous and semifibrous, bags, mill:	41.50–45.50
98% through 325 mesh	49.50
99.4% through 325 mesh	85.00–95.00
Fine micron talcs (origin not specified)	68.00–111.50

The price range quoted in Chemical Marketing Reporter, December 30, 1974, for carload lots of imported Canadian talc, ground, in bags, was from $20 to $35 per ton, f.o.b. works.

The equivalent in dollars per short ton of price ranges for steatite talc, c.i.f. main European port, quoted by Industrial Minerals (London), December 1974, were approximately as follows:

Norwegian:	
Ground (ex store)	$63.00-$70.00
Micronized (ex store)	98.00-159.00
Chinese:	109.00-123.00

No explanation was offered for the fact that these quotations were approximately double those appearing in the same magazine, January through July 1974.

FOREIGN TRADE

Exports.—The quantity of talc-group minerals exported from the United States in 1974 was 2% more than in 1973, and the total value was 1% higher, establishing new alltime highs for both. The largest share of the exported material was shipped to Mexico, followed in descending order by Canada and Belgium; shipments to those three countries accounted for 80% of the 1974 total, and the remaining 12% was distributed among about 50 other countries.

Imports.—Almost one-third more talc in unmanufactured form was imported by the United States in 1974 than in 1973, whether estimated by quantity or by total value. Total value of U.S. imports in the Census Bureau's classification "Talc, steatite, and soapstone and articles of these, not specially provided for" approached $250,000 for the second year in succession, and again as in 1973, more than half of that figure was accounted for by material originating in the People's Republic of China.

Tariffs.—Schedules applicable throughout 1974 provided for import duties on the various classifications of talc as follows: Crude and not ground, 0.02 cent per pound; ground, washed, powdered, or pulverized, 6% ad valorem; cut or sawed, or in blanks, crayons, cubes, disks, or other forms, 0.2 cent per pound; and other, not specially provided for, 12% ad valorem.

Table 6.—U.S. exports of talc, soapstone, and pyrophyllite, crude and ground
(Thousand short tons and thousand dollars)

Year	Quantity	Value
1972	171	5,791
1973	180	6,618
1974	183	6,711

[2] Less than ½ unit.

WORLD REVIEW

Talc-group minerals were produced in at least 45 different countries in 1974. Total world output of these materials was estimated at about 6.0 million short tons, 4% greater than the corresponding figure for 1973. Newcomers to the list of producers were Afghanistan, Ethiopia, and Sudan. It is believed that there may have been significant production also in a few other countries; however, confirming data are not available. About 60% of the world production was classified as talc (or steatite) and 40% as pyrophyllite. Japan was, as usual and by a wide margin, the world's foremost producer and consumer of pyrophyllite.[4]

Finland.—Finland's production of industrial minerals currently amounts to over half a million tons yearly, and approximately one-fourth of that total consists of high-grade talc produced by froth flotation from a mill feed in which talc and magnesite are present in roughly equal proportions. All but a small part of the product is consumed in the country in paper manufacturing, and the export trade is of minor importance.[5]

India.—An industrial association published an updated version of an earlier report that, while emphasizing the mining industry of India and presenting a register of names and addresses of that nation's producers, also outlined the international situation of 17 important industrial minerals—one of which was talc "steatite"—with regard to world occurrences, production, reserves, and export-import trade.[6]

United Kingdom.—The geological occurrence of talc in the United Kingdom and its exploitation, processing, and industrial applications were the principal subjects covered in a government agency publication, the tenth in a series of "Mineral Dossiers." Subdivisions of the report dealt with a number of other aspects of the talc industry in the United Kingdom including resources, uses, specifications, current price, costs, technology, and overseas trade.[7] Talc is produced in the United Kingdom at present only from mines near Baltasound on the island of Unst, the northernmost of the Shetlands group off the northeast coast of Scotland. Limited docking facilities are a major impediment to expansion of those operations, and at least three-quarters of the current talc requirement of the United Kingdom must be supplied by imports, mainly from Norway, France, Italy, and the People's Republic of China.

[1] In addition to the countries listed, Southern Rhodesia is believed to produce talc, but available information is inadequate to make estimates of output levels.

[2] Calendar year Mar. 20, 1974, to Mar. 20, 1975.

[3] Includes talc and wonderstone (pyrophyllite).

[4] Includes talc and pyrophyllite; in addition, pyrophyllite clay is produced as follows in short tons: 1972—[r] 338,401; 1973—[r] 355,095; 1974—466,030.

[5] Data based on Nepalese fiscal year, mid-July 1973 to mid-July 1974.

TECHNOLOGY

A wide diversity of materials are employed as fillers, extenders, and binders in plastics formulations to give products with superior characteristics, and talc is among the substances being used in ever greater quantities for that purpose. The theoretical and mechanical aspects of the functions of fillers for plastics were discussed in an article published in a chemical journal.[8]

A brief outline of the talc industry from the Canadian viewpoint was presented in a magazine article. The dry mill and wet mill flow sheets of Canada's most important talc producer, Baker Talc Ltd., were illustrated.[9]

The physical, mechanical, and electrical properties, maximum recommended operating temperature, and uses of steatite ceramics (in which talc is a major and essential component) were summarized in a published tabulation.[10] Talc was one of the substances making up a coating compound suggested for protecting from acid corrosion the inner surfaces of concrete leaching vats used in increasing numbers in the rapidly evolving hydrometallurgy of copper.[11] It was stated that an abundantly available raw material, Montana talc, can be processed to make a synthetic form of hectorite purer than naturally occurring clay mineral, that has desirable rheological properties for mud, paint, and grease applications. British Patent 1,321,338 reportedly was granted for this application, but other pertinent information was not given.[12]

A patent was issued for a process in which platy talc is recovered and simultaneously separated from accompanying granular and/or acicular talc particles and objectionable foreign substances of gritty texture.[13] Ultraviolet induced fluorescence is applied in a patented procedure to make possible the recovery of high-purity platy talc substantially free from tremolite with which it is closely associated in some ores. After segregation of the white fluorescing fraction (talc) from the nonwhite fluorescing material (tremolite), the final separation is accomplished by froth flotation.[14]

The possible involvement of finely divided, airborne talc in some respiratory pathologies has become a frequent topic for debate in medical, technical, and popular publications. An article in a mining magazine provided a useful review of some of the conclusions reached by investigators of this subject, but a definition of terms could have added to the value of the study. The statement was made, for example, that ". . . results indicate that talc is predominantly cytogenetic . . ." The significance of cytogenetic in this context seems obscure.[15]

Because of the health hazards attributed to certain substances that occur as impurities in some commercial varieties of talc, development of adequate methods of testing for their presence has become an urgent necessity. It was stated that step-scanning X-ray diffraction and transmission electron microscopy are the most reliable of all the currently available techniques for identifying and quantitatively estimating asbestos and asbestiform minerals in talc ores down to fractional-percentage levels.[16]

Thorium

By Roman V. Sondermayer [1]

Supplies from two domestic mines, both in Florida, and imports, mostly from Malaysia, were more than adequate to meet demand for thorium during 1974. Despite a 38% decline in domestic production, about 30% of the newly mined and imported thorium was stored as residues in holding areas. As in the past, there was no direct mine production of thorium. Monazite, the principal source of thorium, was a byproduct of titanium mining and was recovered for its rare-earth content.

Humphreys Mining Co. moved its mining operation from a location near Folkston, Ga., where the reserves were exhausted, to a location south of the State line in Florida.

A weak market continued throughout 1974, but long-range potential for the use of thorium was considered good. Energy shortages in the industrialized countries stimulated a search for new sources of energy. The existence of large resources of thorium in the United States and worldwide encouraged research on the use of thorium as a nuclear fuel and on thorium-fueled reactors. However, lower demand for electric power and increased capital costs for constructing thorium-fueled, high-temperature, gas-cooled reactors (HTGR) resulted in cancellations of orders for new reactors. This trend could adversely affect future demand for thorium.

During 1974, the most significant events concerning thorium were related to research and to industrial activities. Research continued on improvement of the HTGR and on its use as an industrial source for process heat and power generation. Work continued on the light water breeder reactor (LWBR) concept. A demonstration core containing thorium was scheduled for installation in an operating pressurized water reactor (PWR) in 1976.

Preliminary work started on a General Atomic Co. (GA) plant for production of thorium-uranium fuels and on an Atomic Energy Commission (AEC) [2] facility for reprocessing thorium fuels. At the beginning of the year, 10 HTGR's, with a total capacity of 8,000 megawatts electrical (Mwe), were on order. At yearend, one HTGR, a 40-Mwe plant at Peach Bottom, Pa., terminated production of electric power, and orders for two HTGR's had been canceled. The 330-Mwe HTGR at St. Vrain, Colo., was rescheduled for initial operation in 1975.

DOMESTIC PRODUCTION

Mine Production.—During 1974, two mines in Florida were the only domestic producers of thorium. As in the past, thorium was a byproduct of beach sand mining for titanium and recovery of rare-earth elements. U.S. mine production of thorium declined 38% compared with that of 1973. A move to a new mining area by one producer and difficulties in dredging encountered by another caused the decline.

Humphreys Mining Co. moved its dredging operation, including the wet plant, from a location near Folkston, Ga., to a nearby location in Florida; the dry plant remained in Georgia. When normal operations were resumed, wet concentrates from the new mining area were moved by 20-ton trucks to the dry plant at Folkston, Ga.

---

[1] Physical scientist, Division of Nonferrous Metals.

[2] The Energy Reorganization Act of 1974, enacted on October 11, 1974, abolished the Atomic Energy Commission and established the Energy Research and Development Administration (ERDA) and the Nuclear Regulatory Commission (NRC).

Titanium Enterprises, jointly owned by American Cyanamid Co. and Union Camp Corp., was the second domestic monazite producer. At this operation, located near Green Cove Springs, Fla., the company mined a Pleistocene beach sand deposit mostly for ilmenite, rutile, and zircon. As in Georgia, monazite was a byproduct, and suction dredges were the principal mining equipment. During the year, production of monazite was lower than mine capacity. Installation of a new, heavier dredge caused a slowdown in production.

Ethyl Corp., Baton Rouge, La., explored beach sand deposits and operated a pilot plant for recovering monazite near Kentucky Lake, Paris Landing, Tenn. The project was opposed because of possible adverse environmental impact on a nearby recreation area.

Construction of a plant for fabricating thorium nuclear fuels was started at Youngsville, N.C. GA is planning startup in 1978 and full operation in 1979. The plant will use new technology, for which details were not announced. The multimillion-dollar project will have an initial capacity of six cores (24,000 fuel elements) per year and, toward the end of century, the plant will have an annual capacity of 20 cores.

Refinery Production.—The only significant domestic firm processing monazite for thorium was W. R. Grace & Co., Davison Chemical Division, at Chattanooga, Tenn. Lindsay Rare Earths, which was affiliated with Kerr-McGee Chemical Corp., West Chicago, Ill., stopped production in 1973, and was in the process of liquidating stock and preparing to dismantle the plant because of radioactive contamination. At yearend, no decision was made on disposal of the ponds, which contain sludges with an estimated million pounds of ThO_2.

Table 1.—Companies processing and fabricating thorium in 1974

Company	Plant location	Operations and products
American Light Alloys, Inc	Little Falls, N.J	Magnesium-thorium alloy.
Consolidated Aluminum Corp	Madison, Ill	Do.
Controlled Castings Corp	Plainview, N.Y	Do.
Gallard-Schlesinger Chemical Manufacturing Corp	Carle Place, N.Y	Processes oxide, fluoride, and metal.
General Atomic Co	San Diego, Calif	Nuclear fuels.
General Electric Co	San Jose, Calif	Do.
Do	Wilmington, N.C	Do.
W. R. Grace & Co	Chattanooga, Tenn	Processes domestic and imported monazite; produces oxide; stocks of hydroxide and metal powder.
Gulf United Nuclear Fuels Corp	Hematite, Mo	Nuclear fuels.
Do	New Haven, Conn	Do.
Hitchcock Industries, Inc	South Bloomington, Minn.	Magnesium-thorium alloys.
Kerr-McGee Chemical Corp	Cimarron, Okla	Nuclear fuels.
NL Industries, Inc	Albany, N.Y	Do.
Nuclear Chemicals and Metals Corp	Huntsville, Tenn	Do.
Nuclear Fuels Services, Inc	Erwin, Tenn	Do.
Nuclear Materials & Equipment Corp. (NUMEC)	Apollo, Pa	Do.
Do	Leechburg, Pa	Do.
Ventron Corp., Chemicals Div	Beverly, Mass	Metallic thorium.
Wellman Dynamics Corp	Creston, Iowa	Magnesium-thorium alloy.
Westinghouse Electric Corp	Bloomfield, N.J	Processes compounds; produces metallic thorium.
Do	Columbia, S.C	Nuclear fuels.

CONSUMPTION AND USES

Estimated apparent consumption of monazite and thorium compounds was about 200 tons of ThO_2 equivalent. This estimate was based on domestic mine production, imports, and changes in domestic stocks of monazite and thorium compounds. Actual industrial demand was substantially lower; the available monazite supply was processed essentially for its rare-earth content, and most of the thorium-containing residues entered company holding areas.

Based on sales from Government stocks and shipments from processors, U.S. industrial demand was estimated at about 80 tons of ThO_2 equivalent. Of the total, about 40 tons of ThO_2 was consumed in nonenergy sectors of the economy. Principal applications were in Welsbach incandescent gaslight mantles, as a hardener for magnesium-thorium alloys, in desperion hardening, refractories, electronics, and chemical (catalytic) applications. About 40 tons of ThO_2 equivalent was used for producing nuclear fuels and for nuclear research.

Philadelphia Electric Co. announced final shutdown of its 40-megawatt Peach Bottom nuclear electric plant, the company's first thorium-fueled, in October 1974. The plant had served an experimental role in the use of thorium-based nuclear fuels and was scheduled to be decommissioned in 1975.

Louisiana Power and Light Co. ordered two 1,160-Mwe HTGR's from GA in early 1974. The new powerplant, called the St. Rosalie Station, will be sited on the west bank of the Mississippi River between the towns of Alliance and Myrtle Grove in Plaquemines Parish. The schedule calls for operation of the first unit in December 1982. The second unit should be operational at the end of 1984.

Southern California Edison Co. (SCE) canceled its contract with GA for two 770-Mwe HTGR's. Consumer conservation measures resulting in decreased demand for power, as well as difficulties in capital financing, were reported as the main factors in the decision to cancel. While canceling the contract, SCE signed a letter of intent for a feasibility study on the construction of two 1,500-Mwe HTGR's at the same locality.

Table 2.—Status of HTGR development in the United States [1]

State	Station (plants)	Capacity (megawatts electric)	Status	Scheduled start of commercial operation
California	Eastern: Desert 1	770	Canceled	1981
Do	Eastern: Desert 2	770	do	1983
Colorado	Fort St. Vrain	330	Plant in power ascension phase.	1975
Delaware	Summit 1	770	Construction permit application in preparation.	1979

Do	St. Rosalie 2	1,160		1984
Pennsylvania	Peach Bottom 1	40	Final shutdown	1967
Do	Fulton 1	1,160	Construction permit application in preparation.	1981
Do	Fulton 2	1,160		1983
Total	10	8,090		

[1] At yearend 1974.

STOCKS

The Government stockpile, in the form of thorium nitrate, totaled 7,285,200 pounds on January 1, 1975. The thorium stockpile objective was zero during the year. Except for 174,300 pounds of nitrate, all stockpiled thorium-containing materials were available for disposal. About 301,102 pounds of nitrate was sold from the stockpile during the year.

Stocks held by industry were estimated in terms of ThO_2 equivalent, as follows: In monazite, 73 tons; in compounds, 77 tons; and in metal and alloys, 1 ton.

PRICES

The price of monazite concentrate increased on the international market. The average declared value for the imported concentrate was $170 per ton compared with $135 in 1973.

Prices listed by the Davison Chemical Division, W. R. Grace & Co., Chattanooga, Tenn., were in the following ranges, per pound, depending on the quantity of purchase: Nitrate, wire grade, 47% ThO_2,

\$2.95–\$3; nitrate, mantle grade, 47% ThO_2, \$3–\$3.10; ThO_2, ceramic grade, 99.9% ThO_2, \$6–\$12; and ThO_2 nuclear grade, 99.9% ThO_2, \$8–\$12.

Quotations in the American Metal Market on thorium metal in pellets remained steady at \$15 per pound. The pure metal was \$65 per pound.

FOREIGN TRADE

During 1974, the United States exported thorium ores. This was the first significant export of these ores in the past decade.

Imports of monazite decreased below 1973 levels. Malaysia was the principal supplier. Imports of thorium compounds increased, but imports of thorium metal (scrap) decreased. The European countries and Canada were the main suppliers.

Table 3.—U.S. foreign trade in thorium and thorium-bearing materials

WORLD REVIEW

The world thorium industry was small compared with other energy-producing mineral industries. During 1974, Australia, India, Malaysia, Brazil, and the United States remained the principle thorium producers. Thorium processing was widely dispersed among a number of countries. Table 4 lists the principal monazite-producing countries among the market economies.

Table 4.—Monazite concentrate: World production, by country
(Short tons)

Country [1]	1972	1973	1974 [p]
Australia	[r] 5,630	4,725	[e] 4,000
Brazil	[r] 2,303	1,606	[e] 1,650
India	4,504	3,858	[e] 3,300

Total	[r] 14,934	13,116	[e] 11,916

[e] Estimate. [p] Preliminary. [r] Revised.

W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Indonesia and North Korea produce monazite, but available information is inadequate to make reliable estimates of output levels.

[2] Exports.

Australia.—Development began on a new mineral project owned by Allied Eneabba Pty. Ltd., near Eneabba, Western Australia. Among other products, monazite will be recovered at a site near Geraldton. Total cost of the project was reported at $17.2 million.

Westralian Sands Ltd. started a new development program to increase production. Reopening of the concentrator at Yoganup and commissioning of a new dry plant are the principal features of the program.

Brazil.—The Commissão Nacional de Energia Nuclear (CNEN), a Brazilian Government agency, controlled the beach sand industry of Brazil. This industry remained the only producer of monazite in the country.

CNEN, through its Administração da Produção da Monazita (APM), operated workings at Itabapoana (Rio de Janiero) and Cumuruxatiba (Bahia). Monazita e Ilmenita do Brasil (MIBRA), a privately owned company, operated facilities for the production of monazite at Guarapari.

In addition, Grupo do Thorio da Divisoro de Reatores do Instituto de Pesgguisas Radioactivas, in Belo Horizonte, studied and planned different uses of thorium.

Mineral Deposit Ltd. of Australia and the Government of Brazil were planning a joint venture to explore beach sands in Brazil. If new beach sand deposits are discovered, a joint company will be established to mine and market ilmenite, monazite, and associated minerals.

France.—La Rochelle facility, owned by Rhône Progil, was the largest processor of monazite in Europe during 1974. About 5,000 to 6,000 tons of monazite was processed, and 150 to 200 tons of ThO_2 equivalent was recovered. Australia supplied about 75% of French monazite requirements. The United States exported about 78 tons of ThO_2 equivalent, in the form of monazite, to France. This represents the first large U.S. export of thorium-bearing material to France in the past decade.

Germany, West.—Hochtemperatur-Reaktorbau GmbH (HRB), Cologne, which was building a 300-Mwe thorium-fueled demonstration plant at Schmehausen, proposed a marketing program for nuclear process heat. The Arbeitsgemeinshaft Nuklear Processwarme (ANP), a joint venture for the use of nuclear process heat, was established by eight German companies. ANP planned a 750-Mwe reactor to start production in 1982.

India.—Government-owned Indian Rare Earths Ltd. continued as the only mineral sand mining and processing firm in India. The company's mineral division, with offices at Quilon, State of Kerala, operated raw material plants at Manavalakurichi and at Chavara. The average ThO_2 content of India monazite ranged from 8% to 10%. Production of thorium hydroxide (dry) was reported at about 700 tons. Installed capacity for production of thorium hydroxide was 904 tons per year.

WORLD RESOURCES

Resources of thorium in market economy countries were evaluated by the U.S. Geological Survey,[3] as shown in table 5.

Table 5.—Resources of thorium in market economy countries [1]
(Thousand short tons)

State	Recoverable as byproduct or coproduct	Recoverable for grade of 0.1% ThO_2 or higher	Recoverable for grade less than 0.1% ThO_2
Australia	50	--	--
Brazil	150	14.0	--
Canada	580	--	--
Greenland	--	--	750
Republic of South Africa	75	--	--
United States	46	106.5	142
Others	84	--	10

[1] Not shown, because of inadequate data, are resources of Argentina, Sri Lanka, Norway, Uruguay, and several other countries.

TECHNOLOGY

Energy, process heat, metallurgical applications, and isotopes were the principal subjects of research related to thorium. Approximately two-thirds of the thorium research was on energy applications.

In electrochemical studies of thorium in molten LiF–NaF–KF at 500° C a reduction wave was obtained at the nickel and tungsten electrodes. Analysis indicated that Th(IV) was reversibly reduced to the metal with alloy formation between deposited thorium and the nickel.[4]

Separation of trace amounts of thorium and its determination was the subject of another study. Thorium can be separated by reversed phase chromatography from a variety of matrices, especially complex natural silicates.[5]

Energy research was directed toward development of thorium fuels, their fabrication and reprocessing, and standardization and development of reactor concepts. In addition, use of the HTGR as a source of process heat continued to be examined during 1974. Among others, coal gasification, steelmaking, water splitting (hydrogen production), and petroleum production from oil shales and tar sands were examined to determine uses of high-temperature-process heat.

The AEC was planning to accelerate its program to develop technology for the recycling of fuels used in HTGR's. This was part of the AEC thorium utilization program. The proposed accelerated effort included demonstration of fuel reprocessing and refabrication technology for HTGR's.[6]

GA, the only producer of a commercial HTGR, was selected by the American Electric Power System to carry out a joint program to develop the technology for a standardized HTGR.[7] The direct-cycle gas turbine was among research projects at the GA facilities in La Jolla, Calif. This would lead to construction of a commercial plant, possibly in 1979, and commercial service in 1985.

The LWBR program, using the PWR to convert thorium to fissionable uranium-233, was near the final stage. Plans called for the installation of a demonstration core in 1976 to test the concept. Once on the breeding cycle, a LWBR replacement core could be produced without further mining or enrichment of uranium ores. Successful operation of the demonstration core might permit conversion of operating or presently planned PWR's to LWBR cores without extensive and costly changes to existing installations.

Tin

By Keith L. Harris [1]

The world supply of tin trended from undersupply during the first half of the year to a balance between supply and demand by yearend as combined releases of over 24,000 long tons [2] of tin from the U.S. Government stockpile and the International Tin Council (ITC) buffer stock and a world economic downturn helped offset the deficiency between world mine production and world consumption. World mine production dropped 2% from the 1973 level to 228,000 tons. Prices, forced upward by currency problems, tight metal supply, inflation, and speculation during the first half of the year, settled into the lower sector of the ITC price range at the end of the year.

U.S. consumption of primary and secondary tin decreased 13% to 64,700 tons. The major uses for tin were in tinplate, 34%; solder, 24%; bronze and brass, 14%; chemicals including tin oxide, 8%; and babbitt, 5%. Most of the nation's tin, in the form of slabs, bars, and ingots, came from Malaysia and Thailand. Less than 200 tons of tin from mines in Alaska, Colorado, and New Mexico was mined domestically. About one-fifth of the tin used in the United States in 1974 was reclaimed from scrap at about 85 secondary smelters.

The only primary tin smelter-refinery operating in the United States in 1974 was the Texas City, Tex., facility of Gulf Chemical & Metallurgical Co. (GCMC). The major feed to the smelter was tin concentrate from Bolivia's State-owned Corporación Minera de Bolivia (COMIBOL).

The average New York price for prompt delivery Straits (Malaysian) tin in 1974 was 396.266 cents per pound, a significant increase from the 1973 average of 227.558 cents per pound.

In May, the ITC reacted to increased production costs by raising the floor and ceiling prices for tin by 34% and 38%, respectively. The General Services Administration (GSA) sold 23,457 tons of tin from the stockpile through commercial channels.

[1] Physical scientist, Division of Nonferrous Metals.

[2] Unless otherwise specified all units are long tons of contained tin.

Legislation and Government Programs.—GSA continued commercial sales of surplus tin during the year. On April 29, sales of grade A tin from the stockpile were limited to U.S. consumers only, although export of grades B, C, and D tin continued. GSA also limited the amount of tin any one customer could purchase per day to no more than 10% of the remaining tin of each grade. Sales for the year totaled 23,469 tons, of which 23,457 tons were commercial. Shipments for the year totaled 23,554 tons. At yearend there was an excess of 166,948 tons above the 40,500-ton objective, of which 6,822 tons was authorized for sale by Congress. Over 140,000 tons of tin has been released from the Government stockpile since sales commenced in 1962. A bill seeking authorization to sell an additional 100,000 tons of stockpiled tin was submitted to Congress but received no action during the year.

The Office of Minerals Exploration (OME), U.S. Geological Survey continued its program of offering participatory loans for tin exploration up to 75% of approved costs.

The depletion allowance for tin remained at 22% for domestic deposits and 14% for foreign deposits.

DOMESTIC PRODUCTION

PRIMARY TIN

Mine Production.—Domestic production of tin in 1974 was less than 200 tons. Most of the year's output came from Colorado as a byproduct of molybdenum mining. Some tin concentrate was produced at dredging operations in Alaska and placer operations in New Mexico.

The Lost River Mining Corp., Ltd., a subsidiary of P.C.E. Explorations Ltd., was evaluating a tin-tungsten-fluorspar property on Alaska's Seward Peninsula, and entered into a long-term agreement with the Bering Straits Native Corp. Bering received an option to acquire equity interest in any subsequent mining operation while assisting Lost River in financing the $80 million operation. A feasibility study has been completed on mining and milling facilities for a 4,000-ton-per-day open pit operation. Lost River plans to develop an airstrip and deep-water port facilities near the property.

Smelter Production.—The only smelter in the United States is the Texas City, Tex., facility of GCMC. In 1974, GCMC received 5,877 tons of tin in concentrate from Bolivia which formed the base load, together with domestic tin concentrate and secondary tin-bearing materials. GCMC was operating under a 10-year contract negotiated with Bolivia in which Bolivia guaranteed to deliver 6,000 tons of concentrate to GCMC in each of the first 3 years of the contract.

SECONDARY TIN

The United States is the world's leader in the production of recycled, or secondary, tin. The United Kingdom, West Germany, Austria, and Australia also produce secondary tin in significant quantities.

Of the tin recycled during 1974, 89% was an alloy constituent of reclaimed bronzes, brasses, solders, and bearing and type metals. A small amount also remained in chemical compounds. Only 11% of the recycled tin, mostly from new tinplate scrap, found its way to market as metal. This latter volume provided only 2% of the total tin supplied to U.S. consumers in 1974, a proportion which does not vary appreciably from year to year.

Secondary tin furnishes about 25% of the total U.S. tin supply each year. In 1974 secondary tin produced in the United States decreased 8% from the 1973 level to 18,897 tons.

Five companies in 11 States were engaged in the detinning business in 1974. Normally the raw materials used are tinplate scrap and spent chemicals or tinning solutions.

XX Not applicable.

[1] Brass-mill stocks include home scrap, and purchased-scrap consumption is assumed equal to receipts; therefore, lines and total in brass-mill section do not balance.

[2] Omits "machine-shop scrap."

CONSUMPTION

U.S. consumption of primary and secondary tin declined 11% and 20%, respectively, with the total consumption of tin down 13%. The marked decrease in tin consumed for solder, down 9,388 tons, accounted for the majority of the decline. Consumption of tin for tinplate increased 5%, regaining its place as the most important use of tin, after being second to solder in 1973. However, the average amount of tin per short ton of tinplate continued to decrease with an average of 9.6 pounds of tin used per short ton of tinplate compared with 9.7 pounds in 1973. Consumption of tin increased slightly in bar tin, chemicals including tin oxide, and terne metal but decreased in all other sectors. U.S. brass mills consumed 1,013 tons of primary tin and 276 tons of secondary tin compared with the 1973 levels of 1,045 tons and 501 tons, respectively.

[1] Includes secondary pig tin and tin acquired in chemicals.

[2] Includes pewter, britannia metal, and jewelers' metal.

STOCKS

Yearend stocks of plant-held pig tin were 15% above the corresponding period of 1973. Tinplate mills, the largest consumers of pig tin, held 73% of the plant-held pig tin stocks at yearend. During the year, stocks rose to the year high of 9,090 tons in May, then fluctuated, ending the year at 8,952 tons. Tin in transit and jobber-importer held stocks were down from those in 1973 while tin in process and tin afloat to the United States recorded increases.

PRICES

Prices of tin metal on the world markets were influenced by tight supply, inflation caused by higher oil prices, currency problems, and speculation during the first half of the year. In the latter half, prices declined following decreased world demand.

Average prices for the year reached record highs for all markets. The average price for cash tin on the London Metal Exchange (LME) was £3493.61 per metric ton (372.16 cents per pound) compared with £1960.44 per metric ton (218.04 cents per pound) in 1973. The average

Penang price for ex-works Straits tin was M$1,136.63 per picul[8] (354.12 cents per pound) compared with M$686.28 per picul (213.55 cents per pound) in 1973.

The Penang price for ex-works Straits tin began the year at M$820 per picul (255 cents per pound) and rose erratically to the year high of M$1,380 per picul (430 cents per pound) in late April. Profit taking actions caused the price to drop during May but with the upward revision of the ITC buffer stock range, the price climbed up again in June. After June, the Penang price, in general, declined, with the price passing through the ITC established ceiling price of M$1,050 per picul (327 cents per pound) on October 7. The Penang price had remained above the ITC ceiling prices since November 9, 1973. At yearend the Penang price was M$920 per picul (287 cents per pound), just inside the lower sector of the buffer stock range.

The LME introduced a new high-grade tin contract August 1. Prior to the introduction, tin traded on the LME was standard tin of 99.75% purity. With the closure of the Williams, Harvey & Co., Ltd. smelter, the source of standard tin for the LME, supplies of standard tin became scarce, causing the LME to initiate the 99.85% high-grade tin contract.

FOREIGN TRADE

Tin supplied by GSA sales of surplus stockpiled material lowered U.S. dependence on imports, as reflected by a 14% decline in tin metal imports in 1974. Of the 39,602 tons of tin metal imported, Malaysia furnished 52%; Thailand, 15%; Indonesia, 10%; and the People's Republic of China, 8%. Imports of tin-in-concentrate destined for the Texas City, Tex., smelter totaled 5,877 tons, up 31% from the 1973 level. Bolivia supplied all the concentrate.

Exports of metal from the United States more than doubled to 8,415 tons, the majority of which (5,585 tons) was exported prior to the late April GSA export restriction on grade A tin sold from the stockpile.

Small tonnages of secondary tin enter the United States as alloy constituents in recyclable solders or other alloys, or as tinplate or other scrap, dross, skimmings, and residues. These imports are reflected in consumption figures and account for the differences normally encountered between U.S. production and consumption of secondary tin. Imports and exports of tin in alloy such as babbitt, solder, type metal, and bronze are shown in the Minerals Yearbook chapters on "Copper" and "Lead." Ferrous scrap exports, including those of tinplate and terneplate scrap, are not classified separately.

WORLD REVIEW

INTERNATIONAL TIN AGREEMENT

With the price of tin above the ITC established ceiling price from late 1973 until October 1974, and the buffer stock virtually depleted, the ITC, operating under the Fourth International Agreement (ITA), had little option but to review disposals from the U.S. stockpile or raise the ceiling price during the four sessions of 1974.

At the April meeting, producing nations, citing increased production costs, asked for a 40% increase in the floor price. The consuming nations objected to such a large increase. The meeting was adjourned and reconvened late in May after the consuming nations representatives conferred with their respective governments. A compromise was reached and, effective May 30, the price range was revised as follows:

	Previous range		Revised range	
	M$/picul	U.S. equivalent cents/pound	M$/picul	U.S. equivalent cents/pound
Floor price	635	198	850	265
Lower sector	635–675	198–210	850–940	265–293
Middle sector	675–720	210–224	940–1,010	293–315
Upper sector	720–760	224–237	1,010–1,050	315–327
Ceiling price	760	237	1,050	327

Even with the 38% increase in the ceiling price, the Penang price did not drop below the ceiling price until October 8, after GSA had sold more than 23,000 tons from the stockpile and the ITC had sold 845 tons from the buffer stock up to that period in the year.

[2] Includes tin content of alloys made directly from ores.

[3] Tin content of production from Metabol and Pero smelters plus exports by ENAF smelter.

[4] Estimate by International Tin Council.

[5] Estimate according to the 60th annual issue of Metal Statistics (Metallgesellschaft).

[6] Includes small production of tin from the smelter in Singapore.

Australia.—According to a study by the Australian Bureau of Mineral Resources, Geology, and Geophysics, Australia's tin reserves increased from 84,000 tons in 1965 to 326,000 tons in 1973. The reserves could be further increased by improving tin recovery rates from alluvial deposits and sulfide ores, recovery of tin from tailings dumps and complex ores, geochemical and geophysical survey methods for tin, and offshore mining methods.[4]

The Australian Government sold its entire strategic stockpile of tin early in the year because of the world shortage of tin and because Australia has become self-sufficient in tin. Associated Tin Smelters Pty. Ltd. purchased the 400-ton stock which offset its production losses due to labor difficulties during the year.

Renison Ltd., Australia's largest tin producer, started operation of its new heavy-media separation plant, thus increasing mill throughput from 450,000 to 700,000 tons per year. Renison and Consolidated Gold Fields, Australia, Ltd., continued exploration of Tasmania's Mount Lindsay tin prospect during the year.

The Aberfoyle group, consisting in part of Aberfoyle Ltd., Ardlethan Tin N.L., and Cleveland Tin N.L., diversified its exploration efforts in an attempt to reduce its heavy dependence on the price of tin. An exploration group formed by the Aberfoyle group and Cominco Exploration Pty. investigated a copper, lead, zinc prospect in southwest Tasmania.

Reserves discovered by exploration at Ardlethan and Cleveland more than offset the amount of ore mined during the year but increased production costs necessitated the exclusion of 1.5 million tons of previous ore reserves as uneconomic. Reserves for the group were placed at 5.6 million tons of ore containing 41,000 tons of tin compared with 7.0 million tons of ore containing 52,000 tons of tin in 1973.

---

[4] Phillips, W. G. B., and J. Ward. Australia's Tin Resources. 4th World Conf. on Tin, Kuala Lumpur, Malaysia, Oct. 30–Nov. 5, 1974. International Tin Council, London, England, Paper No. 1.2, 14 pp.

At midyear, Metals Exploration N.L. ceased tin mining at its Gibsonvale, New South Wales, alluvial tin mine following exhaustion of payable reserves. The mine and plant were placed on a care and maintenance basis until tin prices rise enough to resume production.

Bolivia.—Of the 29,032 tons of tin-in-concentrate produced in 1974, COMIBOL contributed 19,726 tons, the medium miners 6,439 tons, and the small miners 2,867 tons. Total tin exports were 28,497 tons, 2% over the 1973 level. Empresa Nacional de Fundiciones (ENAF), the national smelting company, increased its metallic tin exports from 6,304 tons in 1973 to 6,938 tons in 1974.

The Bolivian Government reduced royalties on tin exports following a 25% wage increase for tin miners. The private mines objected to the new royalty schedule because the rates are based on c.i.f. market quotes and charged to all exporters, even if they were experiencing losses. The private mines requested a tax based on profits rather than export tonnages. High duties and low returns on capital were cited as reasons for lack of investment in tin mining over the past several years, as reflected in the overall decline in Bolivian tin production.

A $600,000 mineral concentrating plant, under construction at Quime, was scheduled to start operation January 1975. The plant was expected to bring many idle private mines back into operation by upgrading low grade concentrates to secure acceptance in the world market. Badly needed financial aid for the private mines was furnished by a $6 million World Bank loan. The money was used to upgrade existing mines and appraise their resources.

A $24 million line of credit from 12 European banks will be used for projects to increase production at several COMIBOL mines. Installation of tin preconcentration plants, application of new technology to increase tin recovery from ores and tailings, and improvements in transportation, ventilation, and electrical systems were some of the projects specified. A portion of the funds will be used to increase by 30% the output of the Caracoles mine, the site of one of the richest tin lodes found in Bolivia in recent years. A crosscut about 7,000 feet long, connecting two sections of the mine through unexplored ground, cut 16 tin veins. Production at the mine in 1974 was about 1,400 tons and reserves at yearend were 14,500 tons.

Brazil.—About two-thirds of Brazil's tin output was mined in the Rondônia tin district, which includes all of Rondônia plus portions of the adjoining States of Amazonas and Mato Grosso. Mines in Goiás and Minas Gerais supplied the majority of the remainder with small amounts mined in Pará, Rio Grande do Sul, and Amapá. All the tin was produced from placer deposits. Tin reserves were estimated at 120,000 to 130,000 tons in Rondônia and 66,000 tons in the remainder of Brazil. Extensive undiscovered resources of tin possibly exist in southern Rondônia, Mato Grosso, southern Amazonas, Goiás, and southern Pará. Minor occurrences are found in Amapá, Paraíba, Rio Grande do Norte, Ceará, Bahia, Minas Gerais, São Paulo, and Rio Grande do Sul.

The Government stimulated multimillion dollar investment in tin exploration and mining by: Outlawing production by individual prospectors in Rondônia in favor of mechanized operations; increasing the Government controlled tin-in-concentrate price to 85% of the previous month's LME average price; and improving transport infrastructure in western Brazil making western mines more accessible to smelters in the southeast. Through August, the Government had granted 1,488 exploration licenses and 35 mining concessions covering over 150 square miles. The proliferation of mining companies occurred because of the small area allotted for each exploration license.

Although six mining groups consisting of 102 companies were active in the Rondônia area, four groups accounted for virtually all the production. The Mineração Brumadinho Ltda. group, the largest producer, was 60%-owned by Brazilian cement interests and 40% by NL Industries, Inc. The group controlled 17 mining companies, three of which were actively mining in the following five locations: Oriente Novo, São Domingos do Alto Candeias, São Lourenço, Cachoeirinha, and Macisa. Mineração Oriente Novo S.A., a subsidiary of Mineração Brumadinho, will take delivery of a 3-cubic-foot bucket dredge manufactured by IHC Holland early in 1975. The dredge will be installed in the Cachoeirinha area. The Cachoeirinha pilot plant produced about 5 to 10 tons of concentrate per month but with the installation of the new dredge, production could reach 100 tons per month. Output at the Oriente Novo mine was about 135 tons per month, the São Lourenço produced about 60 tons per month, and the Alto Candeias and Macisa mines produced about 20 tons of concentrate per month.

The Paranapanema S.A. group, controlled by a São Paulo businessman, has eight registered mining companies, two of which were mining and six were prospecting. The group's mines at Massangana and Igarapé Preto each produced about 100 tons of concentrate per month.

The Cesbra/Philipp Brothers group, owned 50% by Cia. Estanifera do Brazil (Cesbra), (in which Patino N.V. recently increased its ownership from 33% to 90.8%), and 50% by a Brazilian subsidiary of Philipp Brothers, had 15 mining companies, only 1 of which, Mineração Brasiliense (Mibrasa), was actively mining. Mibrasa operated the only tin mining dredge in Brazil at the Santa Barbara mine. The dredge had produced up to 100 tons per month but production tapered off to 20 to 35 tons per month due to poor ground conditions and lack of rain. In 1975, the dredge will be moved to a new deposit in the Alto Candeias region of southern Rondônia where production of 50 tons per month was anticipated.

The fourth group, Mineração e Prospecoẽs Minerais S.A., owned 60% by a Canadian firm and 40% by a Brazilian company, formed six mining companies, one actively mining, and five prospecting. The Jacunda mine produced about 400 tons of concentrate during the first 8 months of the year. Treatment plants had a capacity of up to 60 tons per month.[8]

Indonesia.—With production of 24,626 tons, 12% above the 1973 level and the highest output since 1957, Indonesia's mine production continued to resist the downward production trends evident with other major world producers. Continued increases in tin output were stressed in Indonesia's second 5-year plan ending in 1979. To attain the increased output, P.N. Timah, Indonesia's State tin mining enterprise, ordered two new seagoing bucket dredges, scheduled to be in operation by 1977. Both dredges will be capable of dredging to 150 feet, have 22-cubic-foot buckets, maximum throughput of 1,275 cubic yards per hour, and about 7 million cubic yards per year capacity based on a 600-hour working month and buckets dredging at 75% capacity. P.N. Timah operated 28 dredges, 5 seagoing, about 300 gravel pumps, and 1 open pit mine during 1974.

P.T. Broken Hill Pty. Indonesia secured an exploration concession at the Kalapa Kampit lode mine in 1971. Dewatering of the mine commenced in 1974 and mining of bulk samples was to start early in 1975. Broken Hill has allocated $3.75 million to the exploration and evaluation program.

Expansion of the Peltim smelter at Mentok scheduled for completion by yearend 1975 involved the addition of three reverberatory furnaces with a new metal refining section. Capacity will increase 18,000 tons to a total of 33,000 tons per year, enabling Indonesia to smelt all its mine output. Concentrate in excess of Peltim capacity was smelted in Malaysia.

Malaysia.—Malaysia continued to lead the world in production, smelting, and exports of tin in 1974. A total of 67,048 tons of tin-in-concentrate was mined, the lowest level since 1965 and down 6% from the 1973 production because of depletion of tin deposits and higher mining costs. At yearend there were 56 tin dredges, 932 gravel pump mines, and 37 opencast, underground, and other miscellaneous mines in operation, reflecting a 5% increase in total active mines through the year. Gravel pump operations, worked for the most part by the same families that own the mines, accounted for 53% of the concentrates produced, while dredging by corporations furnished another 33%. Opencast mines brought in 4% of the ore produced; underground mines accounted for 4% and the remaining 6% came from miscellaneous sources. The tin mining labor force increased 6% to 44,050 workers at yearend.

Metal production, at 83,061 tons was 2% above the 1973 level. Exports of metal increased to 83,878 tons from 79,958 tons in 1973.

In a move to increase domestic control over its economy and correct racial economic imbalance, the Malaysian Government announced a policy of regulating foreign investment in future mergers and takeovers. The goal for the tin industry would be 70% domestic ownership by 1990. The Malay national's (*Bumiputra*) share will be increased from 2% to 30% with the Chinese and Indian share at 40% and foreign ownership at 30%. Tin production has been dominated by Chinese-owned gravel pumps and European-controlled dredging operations. No takeovers or expropriations were envisioned. *Bumiputra* will secure a larger share of new mining areas for gravel pump ventures. The flow of foreign investment capital into the Malaysian economy will continue to be promoted to supplement capital requirements for rapid development.

---

[8] U.S. Embassy, Rio De Janeiro, Brazil. State Department Airgram A-09, Jan. 30, 1975, 22 pp.

In April the Government imposed a variable surcharge on tin as part of a broad-based anti-inflation program. The tax ranged from 0% to 5% depending upon the price, starting when the price went above M$700 per picul (218 cents per pound) and increasing to 5% when the price went above M$1,200 per picul (374 cents per pound).

Perbadanan Nasional Bhd. (Pernas), Malaysia's national mining corporation, announced two tin finds, one off the coast of Malacca and the other offshore from Perak, in its 16,000-square-mile concession off Malaysia's west coast. The size of the finds was not published although the Malacca find was termed "substantial." Further drilling was undertaken to establish the size of the Perak deposit. Pernas was negotiating with overseas companies to exploit the deposits.

A $500,000 feasibility survey of Selangor's Kuala Langat forest reserve indicated rich, deep-seated deposits spread over 40,000 acres. Many deposits occur below 200 feet, well below the maximum operating depth of existing dredges, indicating that the mining of the deposits will cost more than mining the shallow alluvial deposits of the Kinta Valley, the area contributing most to Malaysia's tin output during this century. Four dredges operated in the Kuala Langat district at yearend. Selangor Dredging Bhd. operated two dredges and Petaling Tin Bhd. and Conzinc Riotinto Malaysia Sdn. Bhd. each operated one dredge. The Selangor State Government planned to operate three dredges in the area, the first, costing over $5 million, to go into operation in mid-1976.

Pahang State made available 240,000 acres for tin prospecting in the Pahang Tenggara Development area. The State of Kelantan signed an agreement with Anglo-Oriental (Malaya) Sdn. Berhad for mineral prospecting of an area larger than 50,000 acres. Kelantan has not been a major mining state in Malaysia.

Production of tin-in-concentrate by Berjuntai Tin Dredging Bhd. increased 7% to 3,701 tons during its fiscal year. Building of the No. 8 dredge continued on schedule with a launching of a pontoon in November. The dredge will replace the No. 1 dredge which has been operating in Selangor for about 50 years. The estimated cost of the dredge, at $7 million, was about half the total cost for the seven other dredges the company owned.

Southern Kinta Consolidated Ltd., with output of about 1,600 tons of concentrate in 1974, was refused renewal of a mining title to 100 acres of the Rasa Section in Selangor by the Selangor State Government. Upon appeal, Southern Kinta was informed that the title had been granted to another company. The dredgeable portions of the area would have provided up to 2 years of production for the Rasa dredge.

Tronoh Mines Ltd. and Perak State Development Corp. (PSDC) formed a joint venture to exploit tin reserves in the Batang Padang area adjacent to Tronoh's existing leases. The company, owned 70% by Tronoh and 30% by PSDC, was the first joint venture between the private sector and a State government. A dredge of 800,000-cubic-yard-per month capacity will be ordered to mine the area estimated to have reserves of 122 million cubic yards grading 0.27 pound per cubic yard.

Tronoh later was included in another joint venture in which the Selangor State Development Corp. holds 55%, Charter Consolidated (Malaysia), Sdn. Berhad, 36%, and Tronoh 9%, that will develop deep-seated reserves in southern Selangor. Substantial work will be necessary to complete a feasibility study and mining plan but if findings are acceptable, mining operations could start in 5 years.

Gopeng Consolidated Ltd. acquired 550 acres of mining land in the Mukim, Chenderiang District of Batang Padang, Perak, subject to 30% *Bumiputra* participation required by Malaysia's new economic plan. The need to replenish reserves was evident from Gopeng's declining production, down 12% from the 1973 level, to 2,377 tons of concentrate in 1974.

Conzinc Riotinto Malaysia, a joint venture between Rio Tinto-Zinc (41.25%), Conzinc Riotinto of Australia Ltd. (13.75%), and Bethlehem Steel Corp. (45%), experienced numerous production problems with its new dredge requiring modifications to the treatment plant and design of the dredge itself. Production for 1974 was 350 tons short of its designed capacity of 1,000 tons of concentrate per year.

Pacific Tin Consolidated Corp., the only U.S. company mining tin in Malaysia, showed decreases in total yardage treated and tin recovered in 1974. Dredge No. 8 was shutdown from May to November due to structural failure and collapse of the dredge's digging ladder.

Syarikat Eastern Smelting Bhd. will move its smelting facilities from Penang Island to the mainland. Although the move would allow expansion of the facilities, the main reason for the move was to allow redevelopment of the present 13-acre site into a building complex.

Nigeria.—Production of tin in Nigeria declined for the sixth consecutive year to 5,369 tons in 1974, the lowest level since 1934. Over the past several years, spiraling production costs had lowered the profit margin of operators to a point where significant reinvestment and exploration programs had to be curtailed, forcing rapid depletion of minable ore bodies. Decreased royalties and high prices through the middle of the year gave operators a much needed opportunity to make a profit.

Amalgamated Tin Mines of Nigeria (Holdings) Ltd., Nigeria's largest producer, increased profits to $4.35 million during its fiscal year ending March 1974 compared with $0.99 million in 1973. Over $1.5 million of the profits was invested in much needed earth-moving equipment, two bucket wheel excavators, to begin operation in 1975. The investment, one of the largest in the Nigerian tin industry in many years, could be a precursor to increased mechanization of tin mining. Rising labor costs are forcing mechanization if the mines are to remain competitive in the international market.

South Africa, Republic of.—Rooiberg Minerals Development Co. Ltd. announced plans to open an underground mine at Vellefontein in the Transvaal. Reserves at the new lode mine were estimated at 600,000 tons with an average head grade of 0.7% tin. Development costs will be over $2 million with production to start in 1977. Another $500,000 will be spent increasing capacity at Rooiberg's "C" mine. Rooiberg was also considering construction of a new smelter with enough capacity to smelt the total mine output of the Republic of South Africa and of the Territory of South-West Africa.

Thailand.—Depletion of onshore reserves and increased mining costs caused Thailand's tin production to decline 3% from the 1973 level to 20,018 tons in 1974. Although mining activity increased during the year to a total of 685 mines in operation at yearend, productivity declined. There were 22 dredges, 310 gravel pump and hydraulic operations, and 353 other mines producing tin at yearend. Gravel pump and hydraulic mines provided 47% of the output while dredges provided 33%.

An alluvial deposit off the West Coast of Thailand was discovered by the Boonsoong Tin Dredging Co. and Leighton Mining Co. Indicated reserves of 40 million cubic yards grading 0.34 pound of tin per cubic yard were claimed. No development plans will be made until completion of exploration in mid-1975.

United Kingdom.—Decreased output from Wheal Jane Ltd. was attributed to lower grade ore and lower recovery rates. Wheal Jane, the largest tin producer in the United Kingdom, treated 202,000 tons of ore, recovering 1,457 tons of tin-in-concentrate compared with 1,585 tons in 1973.

Geevor Tin Mines Ltd. increased its tin metal reserves 425 tons to 3,398 tons but its average recovery of tin concentrate per ton of ore treated dropped to 18 pounds during the 6-month period ending September compared with 23 pounds during the corresponding period in 1973.

Marine Mining (Cornwall), Ltd., a subsidiary of Marine Mining Corp. of New Jersey, applied for a lease to mine offshore alluvial deposits in the St. Agnes region. Mining will take place from a mobile platform resting on the seabed. Primary dressing by a wet gravity concentrator will take place on the platform with final treatment to take place onshore.

Zaire.—Zairetain, 50% owned by the

Zairian Government and 50% by Compagnie Géologique et Minière des Ingénieurs et Industriels Belges (Géomines), expanded capacity at its Manono mine to 100 tons of concentrate per month by mid-1974. Expansion to 150 tons per month will be completed in 1975 by recommissioning a washing plant. The mine has reserves for 3 to 4 years of operation at the higher rate. Additional resource evaluation to extend operations would require substantial external capitalization. Production has declined from 2,155 tons of concentrate in 1971 to 973 tons in 1974.

A three-phase plan to merge the tin-mining companies in Kivu Province passed into the second phase when Cobelmin Zaire, a subsidiary of Compagnie Belge d'Entreprises Minières, began administration of Kivumines, Philipp Brothers Sobaki (Phibrake), and Somikubi early in the year. The third phase, to take place in 1975, will bring Syndicat Minière de l'Etain (Symetain) into the merger. Zairian Government participation in the new organization, tentatively to be named Société Minière et Industrielle du Kivu (Sominki), was expected.

TECHNOLOGY

The Fourth World Conference on Tin, organized by the ITC and the Ministry of Primary Industries, Malaysia was held in Kuala Lumpur from October 30 to November 5, 1974. Over 30 papers were presented on subjects ranging from world tin resources, prospecting, mining and processing, and smelting to marketing and consumption of tin. The need to improve resource data and recovery from ores presently mined, especially sulfide ores, and to advance onshore and offshore prospecting and offshore mining methods were stressed. A new method of smelting low-grade concentrate was discussed and trends in consumption and aspects of tin marketing were reviewed. Full proceedings of the conference will be published by the ITC.

The Australian Tin Information Center, the ninth overseas office of the Tin Research Institute (TRI), was officially opened in April. Australia is unique among the major tin-consuming countries because it is also a significant tin producer. The TRI Australian office will provide the technological linkage between producer and consumer as well as the interdisciplinary expertise necessitated by the diversity of tin applications.

A British patent was issued for a pretreatment process to improve froth flotation of tin ore.[6] A relatively low cost collector reagent for the froth flotation beneficiation of cassiterite has been developed.[7]

Kivcet, a Soviet acronym for a oxygen-flash-cyclone-electrothermic smelting process developed in the Soviet Union, has been licensed to a West German firm for use in Western countries.[8] The process is suited to one-step, continuous smelting of complex sulfide concentrates containing copper, lead, zinc, nickel, and other metals such as tin and cadmium. The process is said to have many advantages. If the concentrate contains more than 20% sulfur, the roasting-smelting reaction is autogeneous, actually having a net heat surplus, thus requiring less fuel, electrical energy, and oxygen per ton of charge. During autogeneous smelting the low-volume off-gases are highly concentrated in SO_2 which may be converted directly to elemental sulfur or sulfuric acid. Metal recovery in the matte is very high and the slag is discarded directly from the system because the settling action in the electrical furnace helps free entrained matte from the slag layer.

With an average annual growth rate of 7% to 8%, world consumption of tin in chemicals has increased more rapidly than in any other area over the past 25 years. The TRI reviewed recent developments in organic and inorganic tin compunds.[9] Triorganotin compounds, known for antimicrobial action, have found increasing applications in antifouling paints, timber preservation, and agricultural chemicals. Diorganotin compounds are especially important as stabilizers for polyvinyl chloride and as catalysts in the production of polyurethane foams. Direct uses of inorganic tin compounds in the ceramics and glass industries and as inorganic tin catalysts, as opposed to indirect uses such as those in the electrolyte solution for tin and tin alloy plating or as intermediates in organotin production, account for most of the tin consumed in inorganic chemicals.

Hull fouling costs the U.S. Navy $70 million in added fuel costs per year.[10] Over the life of a ship, 25% of the fuel costs for operating the ship is linked to hull fouling. To prevent hull fouling and to lessen the frequency of hull maintenance, the U.S. Navy has been experimenting with organometallic polymers, the most promising of which appear to be the copolymers of tri-n-butyltin or tri-n-propyltin and methacrylate. In tests at Pearl Harbor, the tri-n-butyltin/tri-n-propyltin methacrylate was still effective against fouling organisms after 3 years in the water.

Research conducted at a U.S. university using triphenyltin acetate and chloride to inhibit the growth of tumors in mice has established that triphenyltin acetate has promise as a potential tumor growth inhibitor.[11]

A new, white metal-bearing alloy has been developed which is claimed to have higher strength, better bonding properties, less sensitivity to cooling rates, less tendency to segregate, superior ductibility, and good machinability.[12] New, stronger, and lower cost alloys for making relays, connectors and springs were developed by a U.S. firm.[13] The copper, nickel, and tin alloys can be 15% stronger and sustain a 40% greater load under repeated bending than copper beryllium, the strongest copper alloy currently used.

A lead-bismuth alloy continuing up to 10% tin was developed for soldering aluminum.[14]

After up to 20 years of observation, the TRI has shown that by careful selection of type and thickness of coating, by choice of substrate, and by various other methods, the risk of spontaneous growth of whiskers on tin coatings can be greatly reduced.[15] Recent developments in tin nickel plating and drawn and wall-ironed can manufacture were reviewed by the TRI.[16]

A new float glass process that allows the glass to be formed at the refining stage before passing over a tin bath, resulting in glass of more uniformity, has been developed by a U.S. firm.[17]

Titanium

By F. W. Wessel [1]

Demand for titanium in its various forms began to decrease during the second half of 1974. Production of pigment during the fourth quarter was 19% below the record high of 216,218 tons produced during the second quarter. Demand from the larger pigment consumers began to decline as early as March. Ingot production held up well during the year, but the backlog of orders for titanium mill products became less. Domestic ore shipments declined about 7%.

Prices moved up sharply during the first half and held at high levels until yearend. The price of pigment was decontrolled April 1, after which it joined other titanium commodities in an upward movement.

Legislation and Government Programs.—About 16,000 tons of rutile was sold from the stockpile early in the year, leaving 39,000 tons on hand. Stockpiled titanium sponge continued to be sold under the "buy-back" provisions of its acquisition to RMI Co. and Titanium Metals Corp. of America (TMCA), its original producers.

The Environmental Protection Agency (EPA) published guidelines for effluent limitations in terms of iron content, acidity, and total suspended solids. A few months later, EPA published a notice of intent to amend these guidelines.[2] An EPA report that included a study of 23 inorganic chemicals, including titanium dioxide, indicated that costs of waste treatment could be passed along to the consumer. In the case of titanium dioxide, such costs would bring about price increases ranging from 0% to 20%.[3]

Table 1.—Salient titanium statistics

	1970	1971	1972	1973	1974

[2] Federal Register. V. 39, No. 49, Mar. 12, 1974, pp. 9624–9625; v. 39, No. 154, Aug. 8, 1974, p. 28536.

[3] Environmental Protection Agency. Economics of Clean Water—1973. December 1973, 120 pp.; available from the U.S. Environmental Protection Agency, Washington, D.C. 20460.

A bill to suspend the 7.5% ad valorem tariff on synthetic rutile became law in October.

Government exploration assistance for rutile, available through the Office of Minerals Exploration, U.S. Geological Survey, remained at 75% of the approved cost of exploration. The depletion allowance for ilmenite and rutile remained at 22% for domestic deposits and 14% for foreign deposits.

DOMESTIC PRODUCTION

Concentrates.—Production and shipments of titanium-mineral concentrate in 1974 decreased 5.2% and 7.1%, respectively; the quantity of TiO_2 shipped decreased 6.0%. Rutile production was 6,266 tons, a decrease of 32.3% from that of 1973. The average grade of concentrate shipped was 57.4%, unchanged from 1973. Increased production from the American Smelting and Refining Co. (ASARCO) mine, Ocean County, N.J., was more than offset by decreased production at the mines of NL Industries, Inc., Tahawus, N.Y.; Titanium Enterprises, Green Cove Springs, Fla.; and Humphreys Mining Co. Humphreys interrupted production to move its dredge and rough concentration plant from the worked-out deposit at Folkston, Ga., to a new deposit at Boulogne, Fla. In moving to Boulogne, the company left its dry mill at Folkston; rough concentrates are trucked 13 miles to Folkston for finishing. Production continued with little change at the mines of E.I. du Pont de Nemours & Co., Starke and Highland, Fla.; and SCM Corp., Glidden-Durkee Div., Lakehurst, N.J.

Reserves at ASARCO's New Jersey deposit were estimated at more than 100 million tons of sand containing 4% heavy minerals.

Table 2.—Production and mine shipments of titanium concentrates[1] from domestic ores in the United States

Year	Production (short tons, gross weight)	Shipments		
		Short tons (gross weight)	TiO_2 content (short tons)	Value (thousands)
1970	867,955	920,964	487,298	$18,626
1971	683,075	713,610	388,802	15,936
1972	695,727	743,401	420,887	17,234
1973	785,268	813,400	467,091	21,041
1974	744,572	755,299	433,310	22,715

[1] Includes a mixed product containing rutile, leucoxene, and altered ilmenite.

Ethyl Corp. held about 2,000 acres of land under lease near Paris Landing in western Tennessee, where the McNairy formation contains ilmenite, rutile, zircon, and monazite. During 1974, the company conducted a pilot operation to obtain process data on the mining and beneficiation of these minerals. The pilot plant operates at about 5 tons per hour, and uses flotation to make a bulk concentrate to send to a conventional dry plant. The test program was to be completed by yearend; however, the company delayed its decision pending completion of the dry-plant test work and the results of further study of the effects of dredging on ground water. The project continued to be opposed by environmental groups, but the company's final decision was expected during the last half of 1975.

Ferroalloys.—Production of ferrotitanium was higher than that of 1973, and was produced solely by Shieldalloy Corp., Newfield, N.J. As in 1973, higher grade alloys accounted for about 75% of the total produced.

Metal.—Production of titanium sponge exceeded that of 1973 by 17.5%; in addition, 5,700 tons was received from the Federal stockpile by the original producers under a "buy-back" provision. Producing companies were TMCA, Henderson, Nev., owned by NL Industries, Inc., and Allegheny Ludlum Steel Corp.; and RMI Co., Ashtabula, Ohio, owned by National Distillers & Chemical Corp. and United States Steel Corp.

Production of titanium ingot was 36,132 tons, a 25% increase over 1973 levels. As in previous years, the following nine companies produced ingot:

Company	Plant location
Crucible Steel Co. of America	Midland, Pa.
Howmet Corp	Whitehall, Mich.
Martin Marietta Aluminum, Inc.	Torrance, Calif.
Oregon Metallurgical Corp	Albany, Oreg.
RMI Co	Niles, Ohio
Teledyne Titanium, Inc	Monroe, N.C.
Titanium Metals Corp. of America.	Henderson, Nev.
Titanium West, Inc	Reno, Nev.
TiTech International, Inc	Pomona, Calif.

There were indications of decreased demand at yearend, originating mainly in the area of commercial aircraft production.

Pigment.—Production of pigment increased 0.3%. Shipments advanced 10.5% over 1973 levels, in spite of the collapse of the market in the last quarter. Rutile pigment accounted for 75% of total production and was produced by all seven manufacturers. Five companies produced anatase pigment, and a small quantity of composite pigment was made. Companies producing pigment during the year, with plant location and nominal capacity, were as follows, in tons per year:

Company and plant location	Pigment capacity	
	Sulfate	Chloride
American Cyanamid Co.: Savannah, Ga	70,000	40,000
E. I. du Pont de Nemours & Co.:		
Antioch, Calif	--	27,000
Edge Moor, Del	--	112,000
New Johnsonville, Tenn	--	228,000
Kerr-McGee Chemical Co.: Hamilton, Miss	--	45,000
NL Industries, Inc.:		
St. Louis, Mo	108,000	--
Sayreville, N.J	115,000	--
New Jersey Zinc Co.:		
Gloucester City, N.J	42,000	-
Ashtabula, Ohio	--	27,000
SCM Corp. Glidden-Durkee Div.: Baltimore, Md	50,000	25,000
Sherwin-Williams Chemical Co.: Ashtabula, Ohio	--	27,000
Total	385,000	531,000

In October, Sherwin-Williams Chemical Co. announced an agreement to sell its pigment plant to SCM Corp.

In May, Kerr-McGee Chemical Co. announced its purchase of 800 acres of an industrial park near Mobile, Ala., on which it intended to construct (1) a plant to produce 50,000 tons of pigment annually, and (2) a plant to produce 110,000 tons of synthetic rutile per year. The rutile plant was to use imported ilmenite until production begins at the company's mineral lands near Camden, Tenn. The synthetic rutile produced will be fed to the new pigment plant and the company's existing pigment facility at Hamilton, Miss. However, it was understood at yearend that although the synthetic rutile plant was under construction and expected to come on line in late 1976, pigment plant construction has been deferred.

E.I. du Pont de Nemours & Co. took an option on about 2,200 acres of land near DeLisle, Harrison County, Miss., on St. Louis Bay, and began work on a test well for waste disposal. The company abandoned plans to build its fourth pigment facility at Brunswick, Ga., because officials in that State refused approval of the company's deep-well waste disposal plans. The firm must meet strict conditions established by EPA and Mississippi State authorities in order to construct the planned chloride-process plant with a 125,000-ton annual capacity; contracts for some equipment items have already been placed. Construction of an additional 55,000 tons of annual capacity at the du Pont plant at Edge Moor, Del., continued during the year.

CONSUMPTION AND USES

Concentrates.—Consumption of ilmenite and rutile increased 5% and 6% respectively, over 1973 levels, but slag consumption declined 9%.

Metal.—Consumption of sponge and ingot increased 33% and 24%, respectively. Shipments of mill products were 20% higher than those of 1973. The backlog of unfilled orders for titanium mill products was reportedly decreasing during the last half of 1974. Demand for titanium condenser tubes in both thermal and nuclear powerplants was strong, however, as was demand from the aerospace industry for titanium castings. New uses forecast during the year were in sporting goods and in rechargeable batteries. Scrap consumed for making ingot was 6% higher than in 1973.

Pigments.—Preliminary figures showed a 5.6% increase in shipments. The plastics industry continued to increase its consumption of pigment from 44,500 tons in 1971 to 94,000 tons in 1974. Orders for pigment declined sharply in the final quarter of 1974; consumers were using inventories, with no indication that these inventories had been reduced to a minimum by yearend.

Laboratory investigation indicated a high anatase-pigment content in the ink on an ostensibly 15th century "Vinland map" and helped to establish the map as fraudulent.

STOCKS

The quantity of rutile in private hands continued to erode during 1974, showing a 27% decrease. Slag inventories were reduced 48%, reflecting the heavy demand and consequent shortages. Ilmenite stocks increased about 1%. Yearend stocks of titanium sponge and scrap increased 97% and 24%, respectively. Industry stocks of various grades of titanium pigment were 88,939 tons at yearend, more than twice the January 1 figure; additions to inventory in November and December totaled 42,000 tons.

Table 7.—Stocks of titanium concentrates in the United States, December 31

1974	107,723	101,301

[e] Estimate. [r] Revised.

PRICES

Concentrates.—Price quotations for ilmenite in domestic markets stood at $38 per long ton until July 1 and at $55 thereafter. Australian ilmenite prices began the year at A$11 to A$12 per metric ton, rose $2 per ton at midyear, and closed in the A$13 to A$15 range. Indian ilmenite sold at £3.95 (US$9.50) per long ton, f.o.b. Indian west coast ports, until May; quotations thereafter were in U.S. dollars, and the price went to $16.50 per long ton. In July, Malayan ilmenite began to be quoted in Australian dollars per metric ton; the price range at that time was A$13 to A$14, but some lots were sold at A$15 before the yearend.

Rutile, bulk, f.o.b. cars at Atlantic, Gulf, and Great Lake ports, began the year at $330 per short ton, rose to the range of $520 to $550 at midyear, and went to $710 per short ton in November. These were spot prices; long-term contracts presumably were negotiated at somewhat lower figures. Corresponding price ranges in Australia, in Australian dollars per metric ton, free in container depot (f.i.d.), rose throughout the year as follows: January 1, $140–$148; January 31, $145–$152; March 12, $165–$180; April 15, $175–$200; May 14, $180–$210; May 31, $200–$240; July 9, $280–$320; and October 4, $290–$330.

Titanium slag remained at $60 per long ton, f.o.b. Sorel, Quebec, throughout the year; however, a 25% price increase was announced, effective January 1, 1975.

Metal.—Domestic sponge began the year at $1.42 per pound. The price increased to $1.50 in February, $1.78 in March, $1.90 in June, and $2.25 in November. Japanese sponge sold in the range of $1.36–$1.38 per pound as the year began, rose to $1.46 per pound in February, to $1.70–$1.75 in March, and to $2 at midyear, at which level it closed the year.

Pigments.—Price increases for the various grades of pigment were few and limited during the first quarter; thereafter, prices were decontrolled by the Cost of Living Council and increased to the range of 26–33½ cents per pound for anatase and 32–38 cents per pound for rutile during the second quarter. In July, further increases took place to the ranges of 30½–38½ and 35–43 cents per pound for anatase and rutile, respectively, and were effective until yearend.

FOREIGN TRADE

Titanium dioxide exports in 1974 amounted to 30,379 tons, a 46% increase over 1973 levels. Of this total, Brazil received 14.6%, other Latin American countries and the West Indies, 23.9%; Japan, 9.8%; the Philippines, 8.7%; other Far East countries, 13.4%; Western Europe, 11.0%; Canada, 8.6%. Exports of unwrought, waste, and scrap titanium were 14% greater than those in 1973; 37% went to the United Kingdom and 32% to Belgium. The average valuation was 98 cents per pound, more than twice that of 1973, indicating increased demand for the better grades of scrap. Exports of wrought titanium (ingots, billets, and mill shapes) were 131% greater than those of the previous year.

Imports of ilmenite from Australia in 1974 doubled for the second successive year. Imports of Sorel slag were essentially unchanged. Imports of rutile were 13% greater than those in 1973. The port districts of New Orleans and Galveston reported receipts of 96,667 tons and 84,885 tons of titaniferous iron ore, respectively.

Table 8.—U.S. exports of titanium products, by class

Year	Ores and concentrates		Metal and alloy sponge and scrap		Intermediate mill shapes and mill products, n.e.c.		Pigments and oxides	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)
1972	1,802	$394	3,510	$2,165	562	$6,265	10,335	$4,882
1973	1,494	353	4,142	3,601	745	8,748	20,769	14,021
1974	3,264	727	4,730	9,288	1,719	19,600	30,379	24,575

Imports of unwrought, waste, and scrap titanium were 48% greater than those in 1973. Of the total, 6,963 tons was sponge, which came from Japan (2,753 tons), the U.S.S.R. (3,541 tons), and the United Kingdom (669 tons). The Japanese sponge bore an average declared valuation of $1.17 per pound; the corresponding figure for Soviet sponge was 98 cents per pound. The U.S.S.R. and the United Kingdom were the principal sources of 2,296 tons of ferrotitanium of all grades, valued at $3.12 million.

Imports of pigment reached a total of 34,996 tons, 42% less than in 1973. Imports constituted about 4% of 1974 consumption.

Capacity for titanium pigment production in Western Europe was estimated at 200,000 to 250,000 tons per year in excess of demand. A strong export market kept this condition from being troublesome during most of the year.

A bill (HR 11830) to suspend the duty on synthetic rutile until June 30, 1977, became Public Law 93–470 in October, and a separate Tariff Schedule of the United States (TSUS) category (911.2500) was set up to report imports of this material.

WORLD REVIEW

Australia.—Early in 1974, a Government spokesman, discussing policy in relation to mineral and energy resources, made the following points: (1) Contracts in foreign trade would henceforth be worded to eliminate the possibility of windfall gains or losses; (2) contracts would provide for long-term renegotiation of prices and for short-term escalation; (3) an increasing portion of mineral products presently exported would be domestically processed, and finished or semifinished items would be exported instead; and (4) overseas ownership of Australian mines would not be allowed to increase, and the Government would progressively reduce it as opportunities arise.

Trade sources indicated east coast production of 327,000 tons of rutile and west coast production of 768,000 tons of ilmenite and leucoxene.

Producers of rutile on Australia's east coast in 1974 were Associated Minerals Consolidated, Ltd.; Minsales (a subsidiary of Union Corp. Ltd. of South Africa), whose operating subsidiaries were Cudgen R.Z., and Consolidated Rutile, Ltd.; Rutile and Zircon Mines (Newcastle), Ltd.; Mineral Deposits, Ltd., and Queensland Titanium Mines Pty., Ltd. (both subsidiaries of NL Industries); and Dillingham Mining Co. of Australia. In 1974 this group of mines also produced 285,000 tons of zircon, 35,000 tons of ilmenite, and 1,000 tons of monazite.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, the U.S.S.R. and the Republic of Korea also produce titanium concentrates, but available information is inadequate to make reliable estimates of output levels.

[2] Titaniferous slag production in Canada and Japan is reported separately. Ilmenite produced in Canada goes almost entirely into slag production; separate figures are not available.

[3] Includes leucoxene.

[4] Production of Comissão Nacional de Energia Nuclear only.

[5] Exports.

[6] Includes a mixed product containing ilmenite, leucoxene, and rutile.

[7] Contains 70% to 72% TiO_2.

In the Bunbury area of Western Australia, the largest producer of ilmenite was Western Titanium, a subsidiary of Consolidated Gold Fields, Ltd. Also producing were Western Mineral Sands, Pty., Ltd., Cable Sands Pty., and Westralian Sands, Ltd. In the Geraldton area, companies included Allied Eneabba Pty., Ltd., A. V. Jennings Mining Co., and Western Mining Corp., Ltd. (WMC), which took over the holdings of a number of corporate entities including West Coast Rutile, Ltd., Black Sands, Ltd., Kamilaroi Mines, Ltd., and Mining Corp. of Australia, Ltd. In addition to ilmenite, the mines in Western Australia produced 74,000 tons of zircon, 3,750 tons of rutile, and 2,500 tons of monazite in 1974.

On Fraser Island in Queensland, site preparation began early in 1974 for a sand operation jointly owned by Dillingham Mining Co. of Australia and Murphyores Holdings, Ltd. The deposit contains 2% heavy sands, and is expected to produce 65,000 tons per year of rutile and zircon, in about equal quantities, plus a small ilmenite byproduct. A wet mill will be built on the island, from which rough concentrates will be barged to a dry mill to be built at Maryborough. Environmental restoration will be conducted on a continuous basis. An initial investment of about $6 million is expected, with the operation to come on-line in mid-1975. Sand reserves were estimated to support 15 years of production.

Associated Minerals Consolidated, Ltd., was reportedly investigating processes for producing synthetic rutile from its growing stockpiles of otherwise unusable ilmenite.

In Western Australia, Allied Eneabba Pty., Ltd., encouraged by the results of 7 months of pilot-plant operation, began building its full-scale plant to produce 50,000 tons of rutile, 200,000 tons of ilmenite, and more than 100,000 tons of zircon annually, together with smaller quantities of other minerals. Rough concentrates will be moved to Geraldton for finishing. The plant was expected to cost $15 million, and to be in production by July 1975. The ilmenite will be exported to pigment plants of E. I. du Pont de Nemours & Co., Inc. in the United States; other products will be sold on the open market.

In the same area, the A. V. Jennings Mining Co. made its initial shipment of ilmenite from Geraldton to Japan. At full production, the output is expected to reach 240,000 tons per year of heavy minerals.

In December, WMC, Australia's leading nickel producer, exercised its option to buy the entire issued capital stock of Black Sands, Ltd., a company holding several mineral-sands deposits, including one at Jurien Bay. Black Sands was formerly owned two-thirds by Kamilaroi Mines, Ltd., and one-third by Mining Corp. of Australia Ltd. The price of the purchase was reportedly $11.5 million; heavy mineral reserves were about 3.5 million tons. Development at Jurien Bay was estimated to cost an additional $5 million. The firm plans to sell rutile and zircon, but to stockpile about 200,000 tons of ilmenite annually, probably with the intention of using it as a raw material for making synthetic rutile. The company has no immediate plans for the Black Sands, Ltd., deposits at Cooljarloo.

Laporte Industries (Holdings), Ltd., began a series of additions to its sulfate-process pigment plant at Bunbury, to add 50% to plant capacity by early 1976. Additional ilmenite supplies will be obtained from Western Titanium, N.L., which was reportedly considering the large-scale operation of a heretofore unworked deposit in addition to their present activity at Capel.

Westralian Sands, Ltd., jointly with Lennard Oil, Ltd., outlined a 2-million-ton body of sand near Gingin, and are planning commercial production.

France.—Thann et Mulhouse was building more capacity at its Le Havre sulfate-process pigment plant. Additions of 22,000 tons per year in 1975 and 13,000 in 1977 will bring total plant capacity to 100,000 tons annually.

Germany, West.—Kronos-Titan GmbH, a subsidiary of NL Industries, began a 22,000-ton-per-year capacity expansion of its sulfate-process pigment plant at Nordenham, now rated at a 44,000-ton annual capacity. The addition was scheduled for completion in 1976.

India.—The Indian Government was understood to have approved a proposal by Kerala Minerals & Metals, Ltd., at Quilon, to produce 48,000 tons of titanium pigment annually by the chloride process. The company also was formulating plans for a 100,000-ton-per-year synthetic rutile plant.

Italy.—In February, the sulfate-process pigment plant of Montecatini Edison, S.p.A., was permitted by authorities at the port of Livorno to resume ocean dumping of effluent from its Scarlino plant for a 6-month trial period. The company also continued construction of its 30,000-ton chloride-process plant at Crotone.

Japan.—Production of titanium sponge in 1974 was 9,825 tons. Power shortages hampered first-half production. An increasing portion of titanium was being domestically consumed, chiefly by the chemical-process industries.

Malaysia.—The Trengganu State Economic Development Corp. announced the formation of Syarikat Lombong Titanium Trengganu Sendrian Berhad, a joint venture with local industry, which began mining ilmenite in February at Bukit Payong. Annual production of 10,000 tons is expected.

Norway.—Kronos Titan A/S, an NL Industries subsidiary, announced a 25% capacity expansion at its 20,000-ton-per-year sulfate-process pigment plant at Fredrikstad. The additional facilities were scheduled for completion early in 1976.

Sierra Leone.—During the year, Bethlehem Steel Corp. increased its share of Sierra Rutile, Ltd., from 60% to 80%. Renewed production from this deposit, formerly controlled by Sherbro Minerals, Ltd., was scheduled for late 1975 or early 1976.

The Parliament of Sierra Leone ratified an agreement giving Bayer-Preussag Mining Co. a 5-year exclusive prospecting right in a 2,000-square-mile area along the southern coast. The company will conduct feasibility studies that will include operation of a pilot plant. Much of the rutile present is part of a lateritic formation, and freeing of the rutile grains is difficult.

South Africa, Republic of.—Quebec Iron and Titanium Corp. (QIT), Canada, was the successful bidder for the 49% share of the Richards Bay titaniferous sand deposit formerly held by King Resources, Ltd. The bid was $4 million. Later in the year, Union Corp. Ltd., a major African finance house, reportedly purchased a 25% share from QIT. The majority share is held by the Industrial Development Corp. of South Africa, Ltd., a Government corporation. Pilot-plant studies begun by King Resources are being continued. Plans for operating the deposit include smelting the ilmenite to make pig iron and Sorel slag, and selling the byproduct rutile and zircon on the open market. Production is expected late in 1977. Reserves are estimated at 41 million tons of ilmenite, 1.5 million tons of rutile, and 3.4 million tons of zircon.

Sri Lanka.—The Sri Lanka Geological Survey Department completed a reserve estimate of the black sand body at Pulmoddai, on the northeast coast. Exposed at mean low tide is a high-grade deposit of 3.26 million tons of heavy mineral, 4½ miles long, up to 300 feet wide, and 8 feet deep. Ilmenite accounts for 70% to 75% of this quantity; rutile, for 10% to 12%; zircon, for 8% to 10%; and monazite, for about 0.4%. The ilmenite is under long-term contract to Japanese interests. Technical difficulties at the China Bay dry plant limited the rutile and zircon output.

TECHNOLOGY

The geological genesis of the heavy-mineral deposits at Green Cove Springs and Boulogne, Fla., was described in a paper that indicated their association with an old beach line, now 25 to 30 miles inland because of regression of the sea.[4] Another paper presented a discussion of the advantages and disadvantages of bulk handling of titanium pigment, as both a dry powder and a slurry, paying particular attention to various means of transportation and storage, and their effect on costs.[5] As prices of pigment increased during the year, Johns-Manville offered pigment extenders based on either diatomite or talc, for use in paints and enamels; PPG Industries, Inc., discussed the similar use of amorphous silica in paint formulations.

A method for significantly reducing the quantity of titanium pigment used in paints was advanced by PPG.[6] Micronized air bubbles are blended uniformly throughout the paint, thereby achieving satisfactory whiteness and opacity.

Olin Corp. and Imperial Metal Industries, Ltd., were reportedly forming a joint company, Marstolin Electrolytic Systems, to market dimensionally stable titanium metal anodes and related titanium hardware for use in chloralkali cells.

Requirements that limit discharge of atmospheric pollutants from motor-vehicle systems in the United States has created a major demand for 409 steel, which contains 1% to 1.5% titanium. This demand in turn created increased demand for ferrotitanium in the United States and elsewhere in the world where vehicles are made for the U.S. market.

A meeting of representatives of major steel companies, several research institutes, and the Bureau of Mines was held in February to discuss substitutes for fluorspar in steelmaking. The basic conclusion was that no one substitute was satisfactory in all applications. However, titaniferous iron ore has been used in open-hearth and electric furnaces. This material does not have the desulfurizing power of metallurgical spar, but it is cheaper and has no pollution potential.

Bureau of Mines researchers published several reports related to titanium during the year.[7]

Tungsten

By Richard F. Stevens, Jr. [1]

On a worldwide basis, tungsten concentrate was in short supply during most of 1974. This resulted in a significant increase in the price quoted by Metal Bulletin (London) to an alltime record high of $106 per short ton unit of tungsten trioxide (WO_3). The average 1974 price doubled over that reported in 1973. Inventories of tungsten concentrate around the world were reduced. Demand eased in the last quarter of the year as indicated by the decreased prices and reduced activity.

While domestic tungsten concentrate production decreased 3% to 7.4 million pounds in 1974, mine shipments rose 11% to 7.8 million pounds. Almost all of this material was obtained from the two continuously operating domestic tungsten mines, one in California and one in Colorado. Reported concentrate consumption increased 6% to 16.3 million pounds. Imports for consumption of tungsten concentrate rose 2% and totaled 11.1 million pounds, the highest level in 17 years. Production of ammonium paratungstate (APT) rose 13% to 14.7 million pounds during 1974 and reported consumption of APT increased 13% to 15.7 million pounds.

[e] Estimate. [r] Revised. NA Not available.

[1] Estimated tungsten content.

[2] Estimated number of persons at mines and mills, at yearend.

[3] Included with primary products.

[4] May include some personnel credited under "Concentrate: Employment."

During 1974 the reported price of shipped tungsten concentrate, f.o.b. mines and custom mills, increased 76% and averaged $75.73 per short ton unit; the quoted European price averaged $79.96 per short ton unit (about $83.93 per short ton unit with U.S. import tariff added).

Legislation and Government Programs.—During the year the General Services Administration (GSA) Office of Stockpile Disposal continued to sell excess stockpiled tungsten concentrate on the basis of monthly sealed bids. At the beginning of the year, GSA allocated 500,000 pounds of contained tungsten monthly for disposal. In April the maximum monthly disposal rate was increased to 650,000 pounds and was further increased to 850,000 pounds per month in May 1974. In early January 1975 the disposal rate was again reduced to 500,000 pounds per month. Under this program, nearly 6.1 million pounds of tungsten contained in concentrate was sold during 1974; 5,129,174 pounds for domestic use and 941,963 pounds for export. In addition 115,421 pounds of tungsten in ferrotungsten and 99,424 pounds of hydrogen reduced tungsten metal powder were sold from Government stockpiles. All of this material was for domestic consumption.

Table 2.—U.S. Government tungsten stockpile materials inventories and objectives

(Thousand pounds, tungsten content)

Material	Objective	Inventory by program Dec. 31, 1974			
		National (strategic) stockpile	DPA inventory	Supplemental stockpile	Total
Tungsten concentrate:

Nonstockpile grade	--	37,051	509	1,153	38,713
Total inventory	--	106,491	4,774	4,457	115,722
Ferrotungsten	--	2,025	--	--	2,025
Tungsten metal powder, hydrogen reduced	--	1,048	--	--	1,048
Tungsten metal powder, carbon reduced	--	717	--	--	717
Tungsten carbide powder	--	953	--	1,080	2,033

A bill (H.R. 1257) to temporarily suspend the duty on tungsten concentrate and on other material in chief value of tungsten introduced in the First Session of the 93rd Congress died when no action was taken during the Second Session. An identical bill (H.R. 2826) was reintroduced early in the First Session of the 94th Congress.

DOMESTIC PRODUCTION

Domestic mine production of tungsten concentrate fell 3% and totaled 7.4 million pounds of contained tungsten during the year. Mine shipments increased 11% to 7.8 million pounds. Although 36 mines in 8 Western States reported production and 35 operations reported concentrate shipments, only 2 mines operated continuously throughout 1974: The Pine Creek mine and mill of the Mining and Metals Division, Union Carbide Corp. (UCC), located northwest of Bishop, Calif., in Inyo County; and the Climax mine and mill of Climax Molybdenum Co., a division of American Metal Climax, Inc. (AMAX), at Climax, Colo., in Lake County. The major mineral value recovered at Pine Creek continued to be tungsten with minor amounts of byproduct molybdenum, copper, gold and silver. UCC processed ore on a "straight through" basis to produce APT, an intermediate form of tungsten suitable for ready conversion to tungsten metal powder.

The major mineral value recovered at Climax was molybdenum. Concentrates of tungsten, tin, and pyrite recovered as coproducts are largely dependent upon the rate of molybdenum production. The maximum tungsten concentrate production capacity at Climax is about 2.5 million pounds of contained tungsten.

Intermittent tungsten concentrate production and/or shipments were also reported from Yuma County, Ariz.; Fresno, Kern, Inyo, Los Angeles, Madera, Mariposa, Mono, San Bernardino, San Diego, Tulare, and Tuolumne Counties, Calif.; Boulder County, Colo.; Valley County, Idaho; Deer Lodge and Granite Counties, Mont.; Churchill, Clark, Mineral, Nye, Pershing, and White Pine Counties, Nev.; Box Elder, Millard, and Tooele Counties, Utah; and Stevens County, Wash.

The Tungsten Queen mine and mill of Ranchers Exploration & Development Corp., near Townsville in Vance County, N. C., remained closed and on "standby" status throughout the year. Ranchers indicated that the facility would be reopened in mid-1975. When operating at capacity, the operation is designed to produce about 2 million pounds of contained tungsten annually from hubnerite ore having an average content of less than 0.5% WO_3. It is anticipated that minor amounts of lead, copper, silver, and pyrite will also be recovered.

In the latter part of 1974 UCC announced plans to develop a new tungsten mine and mill on the Tempiute property in Lincoln County, Nev., about 50 miles northwest of Alamo. The underground mine and adjoining surface mill was scheduled for completion and startup in the third quarter of 1976. When operating at designed capacity, the facility will produce about 2 million pounds of tungsten annually and byproduct zinc concentrate. The scheelite ore at Tempiute will be processed to tungsten concentrate prior to being shipped to UCC's Pine Creek (Calif.) facilities for processing to APT. When in full production, this operation is expected to employ about 90 to 100 workers with an annual payroll in excess of $2 million.

Late in the year, NL Industries, Inc., at Laredo, Tex., began operation of a tungsten concentrate recovery circuit adjacent to the company's Laredo antimony smelter. Low-grade semiconcentrate from Guatemala will be upgraded to synthetic scheelite. Depending on the grade of feed stock, capacity will be about 2,000 tons per year.

Table 3.—Tungsten concentrate shipped from mines in the United States

Year	Quantity			Reported value, f.o.b. mine [1]		
	Short tons 60% WO_3 basis [2]	Short ton units WO_3 [3]	Tungsten content (thousand pounds)	Total (thousands)	Average per unit of WO_3	Average per pound of tungsten
1970	9,785	587,088	9,312	$23,790	$40.52	$2.55
1971	7,173	430,427	6,827	20,184	46.89	2.96
1972	7,401	444,145	7,045	18,104	40.77	2.56
1973	7,418	445,051	7,059	19,154	43.04	2.71
1974	8,233	494,012	7,836	37,413	75.73	4.77

[1] Values apply to finished concentrate and are in some instances f.o.b. custom mill.
[2] A short ton of 60% tungsten trioxide (WO_3) contains 951.72 pounds of tungsten.
[3] A short ton unit equals 20 pounds of tungsten trioxide (WO_3) and contains 15.862 pounds of tungsten.

CONSUMPTION AND USES

The application of tungsten in cutting and wear-resistant materials, primarily as tungsten carbide, increased 22% and continued to represent the major form of tungsten product consumption. This use of tungsten carbide accounted for 60% and tungsten carbide in welding and hard-facing rods accounted for 8% of the total product consumption. In 1974 tungsten product consumption rose 14% to almost 20.6 million pounds of contained tungsten. Other major end-use categories during the year were specialty tool steels (14%) and mill products (13%).

During 1974 the consumption distribution of intermediate tungsten products used to make end-use items was as follows: Tungsten carbide (including cemented, crushed, and cast), 44%; tungsten metal powder (including carbon-and-hydrogen-reduced), 36%; and ferrotungsten and chemicals (including scheelite and scrap for direct addition to steel melts), 10% each.

Figure 2 is a simplified tungsten flow diagram showing the major processing steps, intermediate tungsten products, and major end use items.

Several special review articles were published during the year which evaluated the application of tungsten metal in high-temperature nuclear applications and evaluated tungsten carbide cutting tools.[3]

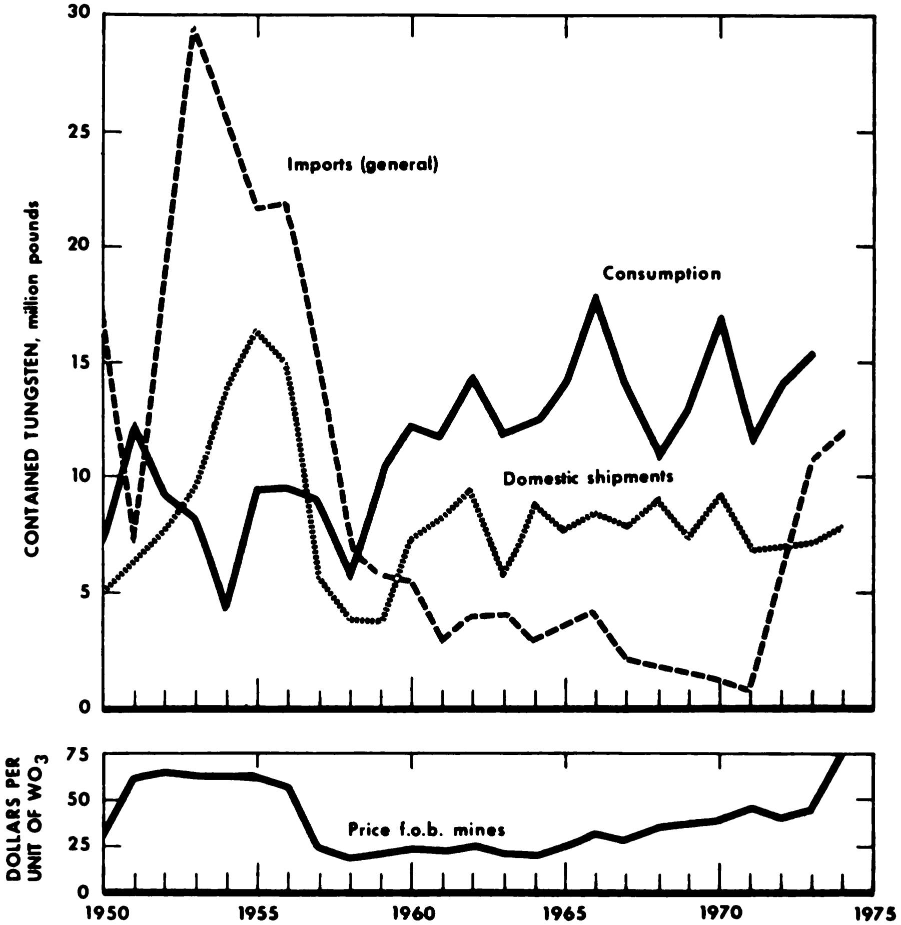

Figure 1.—Domestic shipments, imports, consumption and average price of tungsten ore and concentrate.

[3] Major consumers of tungsten concentrate and APT.

STOCKS

Reported stocks of tungsten concentrate held at domestic mines at yearend 1974 more than doubled and tungsten concentrate stocks held by consumers increased 8% during the year. Stocks of ammonium paratungstate rose 12% over that of 1973. Industry stocks of intermediate tungsten products continued to increase as indicated in tables 1, 4, and 6. Data on stocks of tungsten concentrate held by dealers were not available.

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified."

[1] Includes melting base self-reducing tungsten.

[2] Includes both carbon-reduced and hydrogen-reduced tungsten metal powder.

[3] Includes tungsten chemicals, natural and synthetic scheelite, tungsten scrap and other.

[4] Data may not add to totals shown because of independent rounding.

[5] Includes welding and hard-facing rods and materials and nonferrous alloys.

PRICES AND SPECIFICATIONS

During 1974, the average value of tungsten concentrate shipped from domestic mines and mills as reported to the Bureau of Mines increased 76% to $75.73 per short ton unit of WO_3. Tungsten concentrate for domestic use was purchased from GSA during the year at prices, ex-duty, ranging from $42.10 to $106.28 per short ton unit. For export, the price ranged from $47.75 to $91.88 per short ton unit.

As quoted in the Metal Bulletin (London) and reported in Metals Week the European price of tungsten concentrate, shown in table 7, increased throughout the year from a low in January of £21.00 per metric ton unit (about $41.53 per short ton unit depending upon the prevailing rate of currency exchange) to a high of £50.25 per metric ton unit (about $105.90 per short ton unit) in September.

The price of APT delivered to large volume contract customers was $62.50 per short ton unit at the beginning of 1974. This price was increased to $72.50 per short ton unit in May, to $97.50 per short ton unit in July, and to $116.50 per short ton unit in September. The price of "Blue Oxide" was set at $2 per short ton unit above the APT price plus 1% surcharge to provide for processing losses.

In January a conversion fee of about $11 per short ton unit was charged for "toll" processing tungsten concentrate to APT at a recovery rate of about 96%. At midyear the tolling charge was increased to $14.50 per short ton unit and by yearend 1974 increased to $17 per short ton unit.

The quoted price of carbon-reduced tungsten metal powder, as reported in Metals Week, f.o.b. shipping point, was $4.50 per pound of contained tungsten in 1,000-pound lots in January. During the year the quotations on carbon-reduced tungsten metal powder were discontinued as activity in this material ceased. The price of hydrogen-reduced tungsten metal powder (99.99% purity), f.o.b. shipping point, as quoted in Metals Week, rose from a range of $4.97 to $6.74 per pound of contained tungsten at the beginning of the year to a range of $9.64 to $11.34 per pound at yearend. Within these ranges, the price was primarily dependent upon the tungsten powder particle size (Fisher number).

The price quotations of low-molybdenum-containing ferrotungsten was discontinued during the year. The U.S. dealer price of ferrotungsten for export during 1974, as quoted in Metals Week rose from $4.50 per pound of tungsten in January to $6.00 to $7.00 per pound in December. The quoted price of UCAR, a proprietary high-purity ferrotungsten produced by Union Carbide Corp., 90% tungsten, doubled from $3.98 to $8.20 per pound of contained tungsten during the year.

The price of scheelite concentrate (calcium tungstate) for direct addition to steel melts was believed to be comparable with data reported in table 7.

December	37.50	43.00	79.33	90.68	84.45

[1] Equivalent high and low quotations as reported in Metals Week from Metal Bulletin (London) data; price dependent upon the prevailing rate of exchange.

[2] Arithmetic average of weekly quotations. The equivalent 1974 average price $79.96 per short ton unit; duty $3.97; equivalent average price, duty paid, $83.93 per short ton unit.

FOREIGN TRADE

Exports.—Tungsten concentrate exports during 1974 increased by a factor of 13 and represented excess material purchased from GSA stockpiles. Ferrotungsten exports rose 52% while exports of APT decreased 79%. Exports of tungsten carbide powder, primarily to Canada and Mexico (26% each), and the Netherlands (18%), almost doubled during 1974.

In 1974 exports of unwrought tungsten metal and alloys in crude form, waste, and scrap increased 5% to 709,461 pounds, gross weight, valued at $1,343,674. This material was shipped primarily to West Germany (70%) and to the United Kingdom and the Netherlands (8% each). Tungsten and tungsten alloy powder exports increased by a factor of three during the year to 1,388,643 pounds, gross weight, valued at $8,468,182. This material was exported primarily to Israel (36%), Japan (18%), Canada (10%), the United Kingdom (9%), and the Netherlands (8%).

Exports of tungsten and tungsten alloy wire increased 20% to 270,525 pounds, gross weight, valued at $7,129,629 in 1974 and were shipped primarily to Canada (21%), Japan (20%), the United Kingdom (9%), and Brazil (8%). Wrought tungsten and tungsten alloy exports rose 86% during the year to 288,750 pounds, gross weight, valued at $3,623,183. Most of these exports were shipped to West Germany (47%), Canada (19%), and Japan (9%).

Imports.—Imports for consumption of tungsten concentrate rose 2% during 1974 and totaled almost 11.1 million pounds of contained tungsten, the highest import level since 1957. The major sources of these imports were Bolivia (19%), Portugal and Canada (15% each), Thailand, (14%), and Peru (12%).

Imports of tungsten carbide during the year, primarily from West Germany (65%) and Sweden (34%), decreased 21% and totaled 165,238 pounds of contained tungsten valued at $1,580,411. Imports of waste and scrap containing over 50% tungsten increased by a factor of two and totaled 168,720 pounds of tungsten valued at $693,827. This material was received principally from West Germany (26%), Israel (24%), the Netherlands (18%), and Sweden (13%). Imports of unwrought tungsten (except alloys) in lump, grain, and powder fell 53% to 26,302 pounds of contained tungsten valued at $239,004 and were received mainly from West Germany (64%). Wrought tungsten imports in 1974 increased 47% and totaled 24,588 pounds valued at $1,189,308. This material was imported principally from Austria (75%) and Japan (18%).

Imports of tungsten material classified as "metal-bearing materials in chief value of tungsten" decreased 33% and totaled 201,074 pounds of contained tungsten valued at $715,247. These imports were received from the Republic of Korea (84%) and Thailand (16%). Most of the material imported under this classification was believed to be synthetic scheelite. In addition, 1,062,372 pounds of contained tungsten was imported, all from the Republic of Korea, as ammonium tungstate valued at $4,183,365.

In 1974 calcium tungstate imports, all from West Germany, fell 20% and totaled 30,749 pounds of contained tungsten valued at $394,500.

WORLD REVIEW

During 1974 two international meetings on tungsten were held in Geneva, Switzerland, to discuss methods of stabilizing world prices and to evaluate statistical data on tungsten concentrate trade and product consumption. The Working Group of the United Nations Conference on Trade and Development's (UNCTAD) Committee on Tungsten met in August to consider a paper developed by the UNCTAD Secretariat regarding the feasibility of establishing an International Tungsten Council, similar to the International Tin Council, and/or establishing a system of minimum and maximum prices for tungsten concentrate. The UNCTAD Committee on Tungsten subsequently met in November. The Committee staff continued to canvass, tabulate, and report detailed statistics on tungsten concentrate production, consumption, and world trade and on intermediate tungsten product consumption in its quarterly bulletin "Tungsten Statistics." [3]

In addition, a meeting of many of the world tungsten-producing companies was held in Lisbon, Portugal, in order to prepare a unified "producers program" for presentation at the November UNCTAD meeting. A subsequent meeting was scheduled to be held in La Paz, Bolivia, in April 1975.

Many tungsten-consuming companies of the world, particularly from Western Europe, met in Coventry, England, during June to develop a tungsten price index which would be published in the Metal Bulletin (London).

[e] Estimate.

[1] Data may not add to totals shown due to independent rounding.

Argentina.—A plant was being installed in San Luis Province which, when operational, will have a capacity to process about 510 short tons of tungsten per year.

Australia.—Tungsten concentrate production, almost entirely from King Island Scheelite, Ltd., a subsidiary of Peko-Wallsend Ltd., decreased in quantity but increased in value during the year.[4] During 1974 the trading activities of Warman Equipment (International) Ltd., were absorbed into the tungsten activities of King Island Scheelite, Ltd., and the latter company was renamed Warman International Ltd.

Austria.—Preparatory work on the first major tungsten mine in Central Europe was scheduled to begin in mid-1975 near Mittersill, Salzburg.[5] A joint venture of Metallgesellschaft A.G., Frankfurt Am Main, and Vereinigte Österreichische Eisen und Stahlwerke A.G., (Voest-Alpine) Linz-Donau, (47.5% each), and Teledyne, Inc. (parent of Teledyne Wah Chang), United States, (5%) it is expected to produce about 1,000 to 1,500 short tons of tungsten annually. Presently proven recoverable reserves will support operation of the adjacent ore-dressing plant for 15 to 20 years. During the first 5 years of its operation the mine will recover tungsten ore by open pit mining methods; in subsequent years, underground mining will be employed. The low-molybdenum-containing scheelite ore assays about 0.7% WO_3 which will be processed at the mine/mill site by hydrometallurgical methods to tungsten semiconcentrate (20% to 30% WO_3). This material will be shipped to a processing plant at Bergla, Styria, in southwestern Austria where Voest-Alpine plans to recover tungsten products by solvent extraction techniques. When the refinery comes onstream in late 1976, the products will be APT, tungsten metal powder, and tungsten carbide powder. Output will reportedly equal about 10% of the present European demand. About 75% of the products will be exported with the remaining 25% consumed domestically.

A comprehensive evaluation of the present status of powder metallurgy in Austria was released during the year.[6] Based upon sales, tungsten and other refractory metals form the largest segment of powder metallurgy production in Austria. Production and processing is conducted by Metallwerk Plansee, at Reutte in the Tyrol. About 95% of production is for export.

The combined carbide production of the three major Austrian firms, Metallwerk Plansee, Schoeller-Bleckmann Stahlwerke A.G. and Gebruder Böhler & Co. A.B., ranges from 165 to 225 short tons of cemented carbide annually.

Brazil.—An analysis of the current powder metallurgy in Brazil and its future prospects was released.[7] Cemented tungsten carbides produced by powder metallurgy methods for machining applications was estimated to total 0.2 million pounds in 1973. By 1980 the annual production/demand of tungsten carbide in Brazil is expected to increase to about 0.3 to 0.4 million pounds.

Scheelite tungsten ore mined and chemically treated to WO_3 concentrate in Brazil represents the major raw material for tungsten carbide production.

Studies are being conducted in Brazil to adapt foreign tungsten carbide grades to local conditions. The most important Brazilian powder metallurgy companies are located in the State of São Paulo.

Burma.—Rehabilitation of the Mawchi tin-tungsten mines, which was begun in 1969 under a cooperative aid agreement with the U.S.S.R., was expected to be completed by the end of 1974.[8] Soviet technicians and aid are no longer involved in the Mawchi development project. When completed in early 1975, the present annual production of 875 short tons of mixed tin-scheelite concentrates will be increased to 2,000 tons per year.

Expansion of the Heinda tin-tungsten mine in Southern Burma was scheduled for completion in 1975 at which time the current production of 550 short tons of tin and tungsten concentrates is expected to double.

Rehabilitation of the Hermyingyi tin-tungsten mine in Southern Burma will introduce modern mining methods. Upon completion in late 1975 the output of this operation will reach 1,100 tons of mixed tin and tungsten concentrates per year.

[8] U.S. Embassy, Rangoon, Burma. Industrial Outlook Report Minerals. State Department Airgram A–075, July 2, 1974.

Canada.—In 1974 tungsten concentrate produced by the Canada Tungsten Mining Corp. Ltd. (CTMC) at Tungsten, Northwest Territories, near the Yukon border, totaled 2.8 million pounds of contained tungsten.[9] Although production increased slightly during the year, the overall recovery was 71.5% compared with 80.2% in 1973. The cause of the decreased recovery in 1974 was the presence of abrasive talc like material in the low-molybdenum scheelite ore which averaged 1.45% WO_3 and presented milling problems. During the year, CTMC produced 168,665 pounds of byproduct copper (Cu) from scheelite ore averaging 0.168% Cu.

Since mid-1974 all mill feed was recovered from the developed underground ore body. This underground source is expected to have a life of 8 years at a milling rate of 600 tons per day. The installation of an underground primary crusher and a conveyor for delivering tungsten ore to the surface mill was expected to be completed by mid-1975. At yearend, the ore reserves were estimated at 4,436,000 tons averaging 1.63% WO_3 and 0.23% Cu.

CTMC's leach plant in North Vancouver, British Columbia, operated during the year at an overall recovery of 98%. One additional tank was added to handle the backlog of material.

Special reports on Canadian tungsten operations and reserves were issued.[10]

China, People's Republic of.—Consumption of tungsten in China is likely to expand. Machine tools and other metal working equipment is expected to account for most of the expansion. Since most of the easily attainable deposits of tungsten are believed to have been worked out, future production will have to come from lower grade and more complex ores. With the development of China as a world trader, it is anticipated that it may purchase mining equipment required to work low-grade underground tungsten ores more effectively.

Japan.—An optimistic evaluation of the Japanese tungsten carbide and metalworking industries was released.[11] The report indicated that these industries are expected to grow substantially once the Japanese Government's tight money policy is relaxed. During the year the Japanese Government indicated that it would develop an economic stockpile of tungsten.

Korea, Republic of.—The Korea Tungsten Mining Co., Ltd. (KTMC), continued to be the country's major tungsten producer in 1974, primarily from the Sangdong mine, and accounted for 93.2% of the total South Korean production during the year.[12] KTMC is owned 15.5% by the Republic of Korea Government. Data on Korean production and stocks of tungsten concentrate and production of APT are indicated in the following tabulation for 1974:

Company	Short tons (gross weight)		
	Concentrate		APT
	Production	Stocks	Production
Kaya Industries Co., Ltd	76	NA	..
Korea Tungsten Mining Co., Ltd	4,298	NA	990
Okbang Mining Co., Ltd	92	NA	--
Other companies[1]	146	NA	--
Total	4,612	642	990

NA Not available.
[1] About 8 mines.

The APT plant located adjacent to the Sangdong mine and concentrator began operation in 1973 and is expected to produce about 1,800 short tons of APT annually by 1976.[13] In December 1974 South Korea began to produce tungsten metal powder and tungsten carbide from domestic concentrate (70% WO_3) and APT (90% WO_3). By 1977 the estimated domestic production of tungsten metal and tungsten carbide, based upon estimated APT consumption, could be 925 short tons.

Portugal.—Tungsten production, primarily at the Panasqueira mine, of Beralt Tin and Wolfram (Portugal) SARL, a Portuguese company owned 81% by Beralt Tin and Wolfram Ltd. (London), decreased 2% to 2.4 million pounds of contained tungsten during 1974 mainly as a result of the unsettled labor situation.[14] Sales of tungsten concentrate averaging 75.4% WO_3 rose to nearly 4 million pounds of contained tungsten as all of the stockpiled material which had been accumulated in previous years was sold.

The heavy-media separation plant at Barroca Grande and the mill at Rio operated satisfactorily throughout the year with good metal recoveries. Metallurgical tests indicated that it may be possible to increase the recovery of byproduct copper and zinc. Additional tests indicated the possibility of increasing overall tungsten recovery by the production of an additional low-grade concentrate using a high-intensity wet magnetic separation process.

Despite the high level of unemployment in Portugal, the local labor supply improved only marginally although wage increases were awarded by Beralt in an attempt to maintain a stable work force. The major problem continued to be the recruitment of underground miners. Personnel continued to be hired from the Cape Verde Islands during 1974.

Rhodesia, Southern.—Tungsten mining operations at the Beardmore mine and mill operated by the Messina (Transvaal) Development Co., Ltd., ceased in April 1974 when the ore reserve was depleted.[15] During the year, the plant was altered to re-treat slimes and tungsten containing sands. The overall plant recovery was 71.4%. Tungsten recovery at the slimes treatment plant was 32.3% and 42.2% at the sand plant. Production of scheelite concentrate from these low-grade sources totaled 201,000 pounds of contained tungsten. It was anticipated that the stockpiles of low-grade tungsten containing sands and slimes, which can be economically retreated, will be depleted by yearend.

Turkey.—Development of the tungsten deposit at Uludag, 3 miles southeast of Bursa, was continued by Etibank during 1974. When completed and in operation, about 615,000 short tons of ore will be processed annually to produce about 3,300 tons of tungsten concentrate per year.

The Uludag tungsten deposit was reported to contain 10.7 million short tons of proven reserves and 4.2 million tons of probable reserves.[16]

Development of the Uludag tungsten facilities was delayed by a major fire which occurred early in 1975. As a result of this delay, the mine and mill were not expected to become operational before the latter part of 1975.

Yugoslavia.—A brief evaluation of the powder metallurgy industry and its development in Yugoslavia was published early in 1975.[17] Studies of specialized cemented tungsten carbide (WC) powder metallurgy operations at the University of Zagreb formed the nucleus for the development of WC production plants. The two major producers, Prvi Partizan in Titovo Uzice and Sintal in Zagreb, produced about 35,000 pounds of cemented tungsten carbide for the steadily growing Yugoslavian metal-cutting and mining industries.

TECHNOLOGY

Studies were continued by metallurgists of the Bureau of Mines Salt Lake City (Utah) Research Center and by research scientists in industry in an attempt to develop economic methods for recovering tungsten by solvent extraction from low-grade brine deposits (Searles Lake, Calif.), tungsten mill tailings, and tungsten processing sludges.[18] If the tungsten in these sources could be recovered, the domestic reserves would be more than doubled.

Metallurgical engineers at the Bureau of Mines Albany (Oregon) Metallurgy Research Center continued to conduct studies on the ignition hazards of coal-cutter equipment using tungsten carbide bits.[19]

At the Bureau's Twin Cities (Minnesota) Metallurgy Research Center studies were conducted in an attempt to separate and recover titanium tungsten carbide from the tungsten carbide of scrap carbide dies by magnetic fluid density separation methods.

A thorough evaluation of the various commercial methods currently being used to recover cemented tungsten carbide scrap in the United States and Western Europe was reported.[20]

The effects of certain process variables on grain size, grain type, and microhardness of vapor deposited tungsten and tungsten alloys were evaluated.[21]

Physical metallurgical studies of tungsten alloys for high-temperature applications were conducted under Government funding.[22]

Uranium

By Walter C. Woodmansee [1]

Domestic uranium mine production (in terms of U_3O_8 content in ore) was significantly lower in 1974, compared with that of 1973, principally because lower grade ores were mined and shipped to mills. Mining activity continued high, and the gross ore tonnage produced was greater than that of 1973. Mill production was 13% below the 1973 output. One mill was closed for an indefinite period; another was closed for modernization and expansion; and a third was reopened during the year. At yearend 14 mills were in operation, the lowest number in several years.

Although mine and mill production were lower during 1974, the reduced pace was considered temporary. A number of major new mines and associated mills were planned or under construction in New Mexico and Wyoming, in anticipation of a rapid rise in demand for uranium in the short and long terms. Increasing emphasis was placed on recovering uranium by insitu leaching operations, several of which have emerged as commercial ventures because of improved technology and rising uranium prices. The commercial recovery of uranium from phosphates by the fertilizer industry of central Florida also appeared imminent; one operation was nearing production and others were planned.

Exploration for uranium continued on a large scale, although the success ratio was unimproved. There was increased interest in development of lower grade resources, which may become economic in the near future. According to the Energy Research and Development Administration (ERDA),[2] resources at various forward costs ($8 to $15 per pound U_3O_8) were reduced for the first time in several years, owing to the relatively steep rate of inflation influencing production costs. Resources at costs of $30 per pound U_3O_8, which were first established by AEC in 1973, were also lower. The ERDA office at Grand Junction, Colo., continued its national uranium resource evaluation program, which was planned to provide an improved assessment of potential resources.

In other sectors of the nuclear fuel cycle, uranium enrichment services were increased to both domestic and foreign customers. Delays in developing private nuclear fuel reprocessing facilities may cause a shortage of reprocessing capacity within a few years.

Shortages of investment capital, concern for reactor safety, and energy conservation practices caused further delays in commercial nuclear power development. More than half the nuclear powerplants under construction or scheduled during 1974 were deferred, and a few orders were canceled. Nevertheless, increased development of nuclear power continued to be given high priority in the United States and worldwide. Nuclear power became more attractive from the economic standpoint because of oil price escalation.

Exploration and Reserves.—According to an ERDA survey, 83 active companies reported expenditures of $79 million on exploration in 1974. Total exploration and development drilling footage increased approximately 34% during the year, compared with the 1973 rate. Exploration costs, including drilling, access roads, site preparation, geologic and other technical work, sampling, and logging, ranged from $1 to $12 per foot and averaged $2.07 per foot, a 39% increase over costs in 1973.[3]

Drill rigs were in shorter supply than during the exploration season of 1973. Shortages were also experienced in gamma-logging equipment, supplies, and skilled labor.

Source: Energy Research and Development Administration.

ERDA reported reductions in reserves and identified (reasonably assured) higher cost resources, but estimates of potential resources were higher than those for 1973. The reduction in reserves was attributed to the effects of inflation and to a reevaluation of data for certain deposits.

Reserves at $10 per pound U_3O_8, which were reduced from 340,000 tons to 315,000 tons, were still concentrated largely in New Mexico and Wyoming, which accounted for 85% of the total identified resources.[4] There were 596 properties having resources at $10 per pound U_3O_8 and 2,118 properties having resources at $30.

The U.S. Geological Survey announced a $4.1 million resource program on uranium-related projects for fiscal 1975, to provide more sophisticated and efficient technology for the discovery of new deposits.

ERDA expanded its National Uranium Resource Evaluation (NURE) program to assess potential uranium resources throughout the United States, including Alaska. NURE funds were increased from $2.2 million in fiscal 1974 to $5.7 million in fiscal 1975. Contract aerial radiometric reconnaissance surveys will cover 125 areas and 741,000 line miles by 1980, using computerized, high-sensitivity, gamma-ray spectrometers and magnetic detectors. The resource program also includes hydrogeochemical studies and the sampling of alluvial sediments. Participants will incude ERDA's national laboratories, universities, State agencies, the U.S. Geological Survey, and the Environmental Protection Agency. Data on the airborne and geochemical studies will be placed on open file following completion of each survey.[5]

PRODUCTION

Mine.—Gross uranium ore output was higher than that of 1973, but the average ore grade and recoverable U_3O_8 content were markedly reduced. ERDA preliminary data indicated production, by State, as follows:[6]

State	Mine production [1]	
	Ore (thousand tons)	U_3O_8 content (tons)
New Mexico	2,997	5,400
Wyoming	2,458	4,000
Other [2]	1,661	3,200
Total	7,116	12,600

[1] Includes output of approximately 200 tons U_3O_8 from mine waters and leaching operations.
[2] Colorado, Texas, Utah, and Washington; combined to avoid disclosing individual company confidential data.

About 58% of this output was from open pit mines, 40% from underground mines, and 2% from leaching operations and recovery from mine waters. There were 123 underground mines, 31 open pits, and 19 miscellaneous operations.

Several large new mines were under development in New Mexico and Wyoming. Gulf Mineral Resources Inc., a division of Gulf Oil Corp., started construction of surface facilities in the eastern Grants mineral belt, McKinley and Valencia Counties, N. Mex. Late in the year, plans for shaft sinking were being made. The mine will be served by a 24-foot-diameter, concrete-lined, exhaust vent and ore-hoisting vertical shaft and a 14-foot-diameter, steel-lined, man-hoisting and intake vent vertical shaft. The shafts will be bottomed at 3,500 feet. A mining rate of 5,000 tons of ore per day will yield 9 million pounds U_3O_8 per year. Reported reserves were 100 million pounds U_3O_8.[7]

In May a circular shaft, 14 feet in diameter, was completed at a depth of 1,377 feet at the Johnny M mine of Ranchers Exploration & Development Corp. and HNG Oil Co., also in the Grants district, New Mexico. The mine is situated between the main producing area and the Gulf deposit, 20 miles northeast of Grants. At yearend drifting was underway to the ore body north and south of the main shaft. The ore mining rate will be 700 tons per day, starting in 1975. Ore will be processed at the Kerr-McGee Nuclear Corp. mill in the district.[8]

Fluor Utah, Inc. received a contract for the mine and mill complex of Standard Oil Co. (Ohio) and Reserve Oil & Minerals Corp. at the L-Bar Ranch property, Valencia County, N. Mex. The property is 2 miles northeast of the Jackpile mine. Late in the year, the surface plant was under construction, and a circular shaft,

14 feet in diameter, was collared and ready for sinking to a depth of about 650 feet. The planned ore mining rate was 1,000 tons per day.

In the Church Rock area near Gallup, N. Mex., Kerr-McGee Nuclear Corp. and United Nuclear Corp. also had mines under development.

Kerr-McGee Nuclear Corp. terminated its uranium-mining operations at Shirley Basin, Wyo., and completed land reclamation there in December. At a site 40 miles northeast of Casper, Wyo., in the Powder River Basin, the Bill Smith mine shaft was at 860 feet late in the year. Total planned depth was 950 feet. The mine was scheduled for production in 1976.[9]

At the Exxon Nuclear Co. Highland operation, northwest of Douglas, Wyo., also in the Powder River Basin, a 704-foot vertical shaft, bottomed in November, will serve two mines. Underground development will total 11,000 feet. The operation will produce 1 million tons of ore per year, starting in 1977.[10]

Leased Public Lands.—Mining leases on 43 ERDA-controlled tracts, comprising 25,000 acres, were granted to 26 companies during the year. These public lands are located in southwestern Colorado (38), southeastern Utah (4), and New Mexico (1). On April 23 eight tracts in Montrose County, Colo., were leased; bids on 18 tracts for leasing only to small business enterprises were opened on May 15; and bids on the remaining 17 tracts were opened July 1. The bid to one remaining tract not previously leased was opened on August 26. These lands contain substantial uranium reserves developed by AEC-sponsored exploration on withdrawn lands during the 1950's.

Byproduct Uranium.—An estimated 3.5 million to 4 million pounds U_3O_8 were considered recoverable annually from the wet process phosphoric acid operations of six large phosphatic fertilizer producers in central Florida.[11] Additional quantities could also be recovered from the numerous small operations and from the exported phosphate rock, which constitutes about one-fourth of the output.

Uranium Recovery Corp., a subsidiary of United Nuclear Corp., started construction of a commercial-scale facility at a phosphoric acid plant in Bartow, Fla., in February and planned a second onsite facility, near Mulberry, Fla., 30 miles east of Tampa. A central processing facility will produce 1,000 tons U_3O_8 per year.

Gulf Oil Chemicals Co. operated a mobile demonstration uranium extraction plant at acid process streams near Fort Pierce and Bartow during the year. A recovery process, developed by Gulf Research & Development Co., was being tested. Gulf reported a 96% uranium recovery and a probable viable operation at $7 to $8 per pound U_3O_8.[12]

A third potential producer, Westinghouse Electric Co., was negotiating with phosphate fertilizer producers for an associated uranium operation.

Mill.—Output of U_3O_8 in concentrate was sharply reduced in 1974, owing principally to the processing of lower grade ores. According to ERDA the average milfeed grade was 0.18% U_3O_8, compared with 0.20% in 1973. Because of higher uranium prices, low-grade stockpiles (down to 0.05% U_3O_8) were fed to process, resulting in a reduction in overall average mill recovery from nearly 94% in 1973 to about 93% in 1974. At yearend total operable milling capacity was 25,800 tons of ore per day and about 17,000 tons U_3O_8 per year. The mills were operated at about 80% of capacity. Fourteen mills were in operation, compared with 20 mills in 1972 and 18 mills in 1973.

Table 6 indicates the mill status at yearend 1974. The Western Nuclear Inc. plant at Jeffrey City, Wyo., was in a 2-year expansion program to 1,400 tons of ore per day and 2 million pounds U_3O_8 per year.[13] Atlas Corp. started a new carbonate circuit, and a new 500-ton-per-day acid circuit, designed for vanadium recovery, was being installed.

Source: Energy Research and Development Administration.

In addition to mill closures and ongoing modifications and expansions, new mills were scheduled at three major developing mine sites in New Mexico. At the L-Bar Ranch mine, Laguna area, Standard Oil Co. (Ohio)-Reserve Oil & Minerals Corp. planned a 1,000-ton-per-day mill, operable in 1976. United Nuclear Corp. planned to start construction of a 3,000-ton-per-day facility at its Church Rock mine area in 1975. Gulf Mineral Resources Inc. planned milling facilities at its uranium mine under development in the Grants district.

Commonwealth Edison Co., the Chicago-based utility company, acquired control of the Cotter Corp. uranium operation, including the mill at Canon City, Colo. The Tennessee Valley Authority (TVA) acquired the inactive mill at Edgemont, S. Dak., and other uranium properties formerly held by the Susquehanna Corp.

Uranium Hexafluoride (UF_6).—The conversion plant (U_3O_8 to UF_6) of Kerr-

McGee Nuclear Corp. at Sequoyah, Okla., was scheduled for a doubling of capacity (from 5,000 tons uranium equivalent per year to 10,000 tons per year) by 1978. Kerr-McGee concluded a $26 million contract with TVA for conversion of 26.9 million pounds U_3O_8.

According to ERDA the available annual conversion capacity of 24,000 tons of uranium after the Kerr-McGee expansion, including 14,000 tons of uranium at the plant of Allied Chemical Corp. at Metropolis, Ill., will be sufficient until about 1979.

Enriched Uranium.—ERDA reported total enrichment revenues of $497.6 million in fiscal 1974, including $272.9 million for nearly 7 million separative work units (SWU)[14] to 20 domestic and 16 foreign customers and $224.7 million in advanced payments under long-term fixed-commitment contracts.

Eight industrial organizations were participating in ERDA's Domestic Access Program and Access Permit Program, which provided access to ERDA's classified enrichment technology for qualified companies. Engineering studies were underway to demonstrate the economics of the production of enriched uranium by gas-centrifuge methods. A component test facility, equipment test facility, and component preparation laboratories were under construction at Oak Ridge, Tenn., and probably elsewhere under the Centrifuge Development Program.[15]

Several companies announced withdrawals from joint ventures for private uranium enrichment because of the uncertainties in future demand for enrichment services. Late in the year Westinghouse Electric Corp. and Union Carbide Corp. withdrew from Uranium Enrichment Associates (UEA) following completion of an engineering design for a $2.75-billion, 9-million-SWU, gaseous-diffusion plant. In July, UEA took an option on land in Houston County, Ala., for this plant.[16] The remaining partner, Bechtel Corp., was seeking new participation. In September General Electric Co. announced a decision to withdraw from Cengex Associates, which was designing prototype production facilities for centrifuge enrichment. Exxon Nuclear Co. was the other member. In November Electro-Nucleonics Inc. and Atlantic Richfield Co. formed Centar Associates, which announced a joint study for a 300,000-SWU enrichment facility, also by centrifuge methods.

Effective June 30, 1974, AEC announced a temporary suspension of new long-term contracts for enrichment services, pending a review of projected capacities and demand. In order to encourage private development of new enrichment capacity, AEC offered to consider the payment of cash differentials between company and customer terms and the support of private capacity with AEC preproduction stocks.

The ongoing ERDA Cascade Improvement Program and Cascade Uprating Program will expand annual capacity from 17.2 million SWU to 27.7 million SWU by 1980 with new equipment and increased power levels. This capacity was expected to be adequate until the mid-1980's. ERDA planning was under review because of new factors influencing future demand—reactor deferrals and delays, foreign enrichment capacity, setbacks in fuel reprocessing and plutonium recycle, and the rush of new orders in 1974 for enrichment services because of the petroleum crisis.[17]

Principal source: Energy Research and Development Administration, Office of Industry Relations.

Fuel Fabrication.—Several significant developments took place among the nuclear fuel manufacturers. General Atomic Co. sold its oxide fuel facility at Hematite, Mo., to Combustion Engineering Inc.; transferred its equipment from the plant at New Haven, Conn., to San Diego, Calif.; negotiated with Babcock and Wilcox concerning transfer of fuels contracts to that company; and sold its equipment and contracts for special metallic fuels to U.S. Nuclear Co. Exxon Nuclear Co. completed an expansion at Richland, Wash.

ERDA reported that 2,076 tons of enriched UF_6 was shipped for domestic nuclear fuel use and 794 tons to foreign agencies in fiscal 1974, compared with 1,613 tons and 880 tons, respectively, in fiscal 1973.

Fuel Reprocessing.—As in 1973 there was no operable commercial spent fuels reprocessing capacity during 1974. Construction at the 1,600-ton-per-year facility of Allied General Nuclear Services, Inc., at Barnwell, S.C., reportedly was 80% completed, and the plant was scheduled for operation in 1976. This capacity could serve approximately 60 commercial reactors. The only other plant expected to be in operation before 1980—that of Nuclear Fuel Services, Inc., at West Valley, N.Y.—has been closed since 1972 and was under modification to improve environmental protection and was under expansion to 825 tons per year. In July General Electric Co. announced that its new plant at Morris, Ill., which employed new reprocessing technology, was not operable. No plans were made for further work there.

ERDA projections indicated a shortfall in reprocessing capacity continuing through 1985. The situation could be worsened by further slippages in scheduled future capacities. The principal reasons given for the insufficient planned commercial capacity were the uncertainties in Government policy and licensing requirements for plutonium recycle and waste management and problems in investment capital. A backlog of 8,800 tons of unprocessed spent fuel was anticipated, containing 70 tons of plutonium that would not be available for recycle. This would be equivalent to the need for an additional 10,000 tons U_3O_8.[18]

Waste Management.—An ERDA decision was pending on the disposal and control of high-level radioactive wastes, generated during spent fuels reprocessing. A Retrievable Surface Storage Facility (RSSF) with continual surveillance was favored as an interim procedure with either water-immersion or air-convection cooling and sealed-cask storage. As a permanent measure, the concept of underground storage in salt beds was still preferred. In September ERDA issued a draft Environmental Impact Statement (EIS) on the various options in waste management.[19] Public hearings were held in November and December, and a final EIS was in preparation at yearend. ERDA estimated that the cost for waste management to the end of the century would be on the order of $2.5 billion to $3 billion.

Three commercial companies operated six burial sites for low-level wastes on State and Federal lands. An estimated 1.8 million cubic feet of commercial low-level wastes were buried at these sites during 1974, and 1.3 million cubic feet were buried at ERDA facilities.[20]

CONSUMPTION AND USES

During 1974 the domestic commercial nuclear power industry was beset by problems in raising capital and in public concern for reactor safety. In addition energy conservation practices resulted in reduced energy forecasts, which added to delays in nuclear powerplant schedules. Numerous reactor deferrals and a few cancellations were announced. Deferrals affected more than half of the nuclear powerplants under construction or planned during the latter half of the year. As a result, ERDA's short-term (to 1985) demand projections were reduced from earlier forecasts, but the long-term forecast (to 2000) was little affected.

Despite these adverse factors, the industry continued to move forward. According to ERDA 14 plants (11,800 Mw) became operable, the highest number for any year to date. Domestic reactor status was as follows, at yearend:

Status	Number of installations	Capacity (megawatts electric)
Operable	[1] 55	36,810
Under construction	73	73,840
Planned	107	122,070
Total	235	232,720

[1] Includes two ERDA-owned plants.

[20] Energy Research and Development Administration. The Nuclear Industry 1974, WASH-1174-74, pp. 64–73.

This compares with 199 units and 187,779 Mw at yearend 1973. The setbacks in schedules and planning in 1974 were reflected in a sharp reduction in reactor orders or letters of intent (22 in 1974, 46 in 1973, and 36 in 1972), according to a study conducted by the American Nuclear Society.[21]

Table 8.—Current and projected domestic U_3O_8 demand [1]
(Short tons)

Year	Demand	
	Annual	Cumulative
1974	9,700	9,700
1975	10,800	20,500
1976	14,100	34,600
1977	17,500	52,100
1978	20,500	72,600
1979	23,200	95,800
1980	25,800	121,600
1985	50,900	328,900
2000	172,800	2,046,700

[1] Feed materials required for enrichment services. Enrichment tails assays—0.20% to July 1, 1976, 0.275% to July 1, 1981, and 0.30% thereafter.

An ERDA survey of uranium producers, utility companies, and reactor manufacturers indicated reduced uranium-buying activity and a sharply lower rate of increase in delivery commitments.[22] Consumers experienced difficulties in finding available supplies. The prevailing sellers' market was a reversal of the buyers' market existing in previous years.

Organizations were formed or in planning to pool enriched uranium purchases. The World Nuclear Fuel Market, which had 50 charter members including foreign members, was formed by the Nuclear Assurance Corp. A Separative Work Administration Pool comprised 12 utility companies. A Separative Work Units Corp. was organized by the Nuclear Exchange Corp. A fourth agency was the NUS Corp.

Table 9.—Current and projected domestic commercial uranium delivery commitments
(Short tons U_3O_8)

Year	Commitments [1]	
	Annual	Cumulative
1974	11,900	[2] 67,500
1975	15,600	83,100
1976	12,600	95,700
1977	12,700	108,400
1978	15,300	123,700
1979	13,900	137,600
1980	11,600	149,200

[1] In the post-1980 period, through 1994, an additional 42,100 tons have been committed. In addition, 10,600 tons have been committed to foreign buyers, of which 7,000 tons were delivered prior to yearend 1974.

[2] Pre-1974 deliveries were 55,600 tons.

Table 10.—Uranium fuel supply arrangements for domestic nuclear reactors [1]
(Percent of total nuclear generating capacity)

Source of supply	First core	Reloads [2]											
		1	2	3	4	5	6	7	8	9	10	11	12
Primary producers	30	29	25	22	17	17	11	6	4	4	2	1	1
Reactor manufacturers	27	25	21	18	14	10	8	6	4	2	2	2	2
Imports	4	4	4	4	6	4	4	6	6	7	7	8	6
Total	61	58	50	44	37	31	23	18	14	13	11	11	9

[1] As of yearend 1974. Includes reactors operating, under construction, and scheduled totaling 216,000 Mw. Does not include leases from AEC, which are small, comprising less than 0.2% for first cores and for refueling through sixth reload, when they are scheduled to terminate.

[2] Refueling estimated on annual basis.

Source: Energy Research and Development Administration.

Late in 1973 Offshore Power Systems Inc. (Westinghouse Electric Corp. and Tennessee Oil Co.) started dredge-and-fill operations at Jacksonville, Fla., for its manufacturing plant for barge-mounted nuclear powerplants at offshore sites. Construction continued on schedule for completion in late 1975 and first delivery in 1979. However, plans for the first offshore sites in coastal New Jersey may be delayed by as much as 5 years, and other orders or letters of intent remained uncertain.

Studies were underway on the feasibility of nuclear energy centers (NEC), which would include a concentration of nuclear powerplants, process heat for other industries, nuclear fuels manufacturing, fuels reprocessing, and waste management, all at one site. Authorities considered that the NEC concept may alleviate some reactor-safety problems and may also provide better safeguard practices against undesirable diversion of plutonium or enriched uranium.

[22] Energy Research and Development Administration. Survey of United States Uranium Marketing Activity. ERDA-24, April 1975, 26 pp.

Depleted Uranium.—A penetrator for use in ammunition for Phalanx, a naval gun system under research and development, was made from depleted uranium (DU). DU is processed from UF_6 gas, the form in which it occurs in enrichment plant tailings, to a metallic rod form from which the penetrators are cut and worked to specifications.[23]

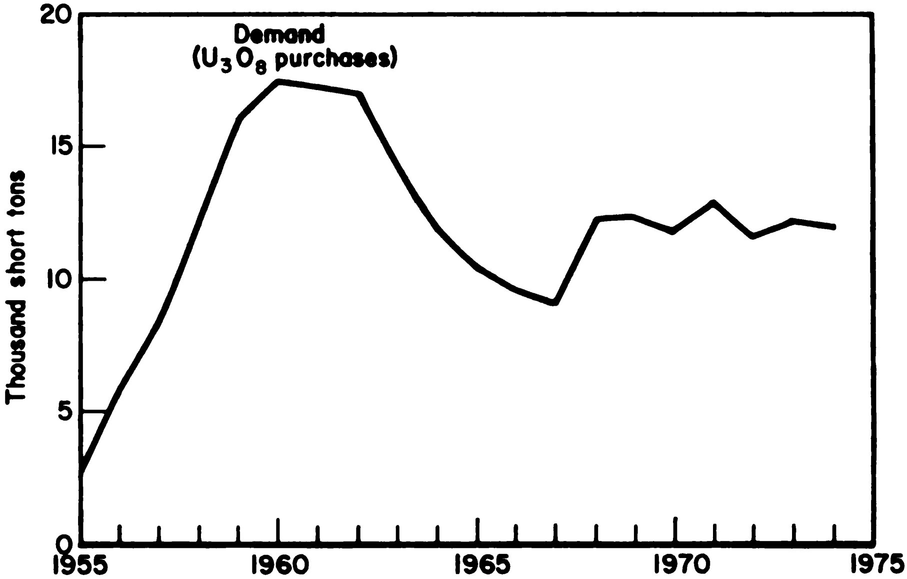

Figure 2.—Domestic uranium demand.

STOCKS

Total stocks held by the producers, or milling companies, were reduced during 1974, whereas those held by the consuming industry were slightly higher, as indicated in the following data provided by ERDA (in tons U_3O_8):

	Jan. 1, 1974	Dec. 31, 1974
In ore at mills	113	284
In process at mills	328	440
In concentrate at mills	5,238	4,302
In concentrate held by utility companies, reactor manufacturers, and agents (including equivalent U_3O_8 in UF_6)	19,900	20,200
Total	25,579	25,226

The stockpile of DU continued to grow as a result of large-scale enrichment services provided for domestic and foreign customers. ERDA announced that 220,000 tons of DU had accumulated in the form of UF_6.

[23] Tabb, B. H., Jr. Phalanx and Its Ammunition. Nat. Defense, March–April 1975, pp. 399–401.

PRICES

The prices for spot sales and future delivery of U_3O_8 in concentrate continued to escalate during 1974. According to the Nuclear Exchange Corp. (Nuexco), the bid price was $7 per pound U_3O_8 for delivery in January and $15 at yearend. During this period, the bid price for delivery in 1980 increased from $12 to $25.35.[24]

An AEC survey illustrated the significantly lower U_3O_8 prices paid by reactor manufacturers and utility companies in contracts negotiated from 1967 to mid-1974.[25] Under the terms of these early contracts, the average price was $7.65 per pound for delivery in 1974 (current price in year of delivery) and $11.40 in 1980. The AEC commented that this survey involved only a small part of projected requirements to 1980 and was not indicative of prices in contracts later in 1974, which were higher.

The strong seller's market developing in 1974 was reflected in newly negotiated contracts, many of which called for prepayments, price adjustment, or price renegotiation at time of delivery. High future uranium prices were indicated in a number of sales contracts announced during the year. Rio Algom Mines, Canada, concluded contracts for delivery during the 1980's at an average price of $20 per pound U_3O_8, subject to escalation and to a Canadian Government requirement that the price be tied to the prevailing world market price at time of delivery. A contract between Western Nuclear Inc. and a European customer was for 2.5 million pounds at $9 per pound for delivery in 1974 and $12 for delivery in 1977, subject to possible 100% escalation. Reported contract terms for sales by Kerr-McGee Corp. to domestic and foreign customers were in the $15- to $16-per-pound range for delivery in the late 1970's. Other sales appeared to be in the range of $13 to $16 per pound for delivery during 1975–80, also subject to price escalation.

Effective December 18, 1974, AEC announced higher prices for enrichment services because of increasing actual and projected costs, primarily for electric power. For the old requirements-type contracts the price, per SWU, was increased from $39.30 to $47.80. Under the new long-term fixed-commitment contracts, the new price, per SWU, was $42.10 (formerly $36.80). Starting in mid-1975, an automatic 2% increase will take place every 6 months.

In August AEC announced plans to request revision of the Atomic Energy Act and the Uranium Enrichment Services Act in order to establish a commercial charge for enrichment services. Existing AEC policy was for cost-recovery pricing, whereas forecasts for the developing private enrichment services were much higher (estimated average $75 per SWU, subject to escalation from 1974, over a 25-year fixed-commitment contract).[26]

FOREIGN TRADE

Uranium was imported in the form of U_3O_8 for conversion of UF_6 and enrichment, and as UF_6 for enrichment. Exports of the enriched uranium product are included in special nuclear materials. Imports of U_3O_8 concentrate were lower in 1974, but imports of other compounds (UF_6) were higher.

In the Federal Register of November 27, 1973 (38 CFR 32595), AEC proposed a revision of the Uranium Enrichment Services Criteria as they apply to the restriction on enrichment of feed materials of foreign origin for use in domestic facilities, pursuant to Subsection 161V of the Atomic Energy Act of 1954, as amended. The proposal was for a gradual relaxation and eventual termination of the restriction according to the following schedule:

Year	Maximum annual feed material of foreign origin, per customer (percent)
1977	10
1978	15
1979	20
1980	30
1981	40
1982	60
1983	80
1984	100

[27] U.S. Atomic Energy Commission. AEC Puts Into Effect its Previously Announced Plan To Remove Restrictions on Enrichment of Foreign Uranium for Domestic Use. News Release No. T-517, v. 5, No. 44, week ending Oct. 30, 1974, pp. 7–8.

WORLD REVIEW

Because of potential international oil supply problems, the oil price squeeze, and escalating prices for coal, foreign government energy policies and foreign utility companies placed increased emphasis on nuclear energy as an alternative to coal and petroleum for the generation of electricity. This was the situation among the industrialized foreign nations, particularly Western Europe and Japan, where forecasts of energy demand necessitated ambitious nuclear development programs. The developing nations were also formulating nuclear programs or placing greater emphasis on nuclear power. Tables 12 and 13 indicate the foreign nations having operable and planned nuclear powerplants. According to data compiled by the American Nuclear Society, 98 plants were operable in 18 countries, and 149 units were planned in 27 countries at yearend 1974. Most of those planned were scheduled for completion by 1985.

Despite these ambitious nuclear programs, deterrents were developing and were expected to influence future nuclear power programs. As in the United States, financing was problematical, and public attitude concerning environmental effects and reactor safety became a more significant issue. Special banks and investment companies were established for capital investment in nuclear power. It was also proposed that the oil-producing countries "recycle" their oil profits in nuclear development in Europe.

Available industrial capacity and manpower, reduced economic growth, and energy conservation practices also influenced planning for future primary and enriched uranium supplies. Western Europe and Japan continued to rely on enrichment services from the United States for the short term. The following tabulation indicates capacity and demand for enrichment services in Western Europe during 1975–85 (in SWU per year):[28]

	1975	1980	1985
Demand	3,500	10,000	23,000
Productive capacity	300	4,000	19,000

Table 12.—Operable foreign nuclear powerplants in 1974[1]

[28] Nuclear News. Reports on Nuclear Programs Around the World. V. 18, No. 3, February 1975, pp. 39–44.

Demand in excess of production would be met primarily by enrichment services in the United States. The tripartite centrifuge enrichment project (United Kingdom, West Germany, Netherlands) proceeded toward development of enrichment facilities of 200,000 SWU each at Almelo, Netherlands and Capenhurst, United Kingdom. The organization had firm orders for 11 million SWU for future delivery and planned annual capacity of 2 million SWU by 1980. In October the first loading of gas centrifuge enriched fuel took place at a small reactor in the Netherlands. The uranium was enriched to 2.8% U_{235} at Almelo.

Construction on the multinational Eurodif gaseous diffusion enrichment project was advanced because of the improved European and world market for enriched uranium. In May a site was selected at Tricastin, France, where electric power will be supplied by four 900-to-1,000-Mw pressurized water reactors. The plant was scheduled for startup at 3.5 million SWU in 1979 and ultimate capacity of 9 million SWU in 1983. In addition to France, the principal participant, interests were held by Italy, Belgium, and Spain. Sweden terminated participation in March. Late in the year, Iran assumed participation through a joint French-Iranian company.

The European Economic Community (EEC) established a goal for nuclear power of 50% of total energy output in 1985. EEC nuclear capacity, 20,000 megawatts in 1974, was scheduled to increase tenfold to 200,000 Mw by 1985. Firm plans were established for 170,000 Mw by 1985.[29]

According to a survey conducted by the International Atomic Energy Agency (IAEA), the oil price rise made the economics of nuclear power more attractive among the developing nations. Before the quadrupling in oil prices, only nuclear power units exceeding 400 Mw were considered feasible in terms of demand, capital, and supporting facilities in the developing nations. Since the oil price rise, nuclear units as small as 100 Mw were considered feasible. Despite this economic advantage, only 8 of 50 developing nations surveyed by IAEA had nuclear powerplants operating or under consideration.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Australia, Brazil, Czechoslovakia, Finland, East Germany, West Germany, Hungary, India, Japan, the People's Republic of China, and the U.S.S.R. are believed to have produced uranium oxide, but information is inadequate to make reliable estimates of output levels.

[2] Produced in part from imported material.

Australia.—Established uranium reserves continued to rise during 1974. Pancontinental Mining Ltd. (65%) and Getty Oil Development Co. (35%) reported a number of increases in reserve estimates as exploration continued at the Jabiluka 1 and 2 deposits, Northern Territory. At yearend, reserves at the Jabiluka were reported at 115,200 tons U_3O_8, making it Australia's largest uranium deposit. Estimates of Australia's measured and indicated uranium reserves, most of which are recoverable at costs of $10 per pound U_3O_8, were as follows, as of January 1, 1974:[30]

Location	Deposit	Reserves (tons U_3O_8)
Northern Territory	Ranger	110,600
Do	Jabiluka 1–2	115,200
Do	Nabarlek	11,600
Queensland	Mary Kathleen	11,000
Do	Mount Isa, Westmoreland	17,300
South Australia	Beverly	19,300

[29] Chemical Week. Winds of Change Give Atom Energy Plants Big Push. V. 115, No. 9, Aug. 28, 1974, pp. 20–24.

[30] U.S. Embassy, Canberra, Australia. Uranium Reserves and Export Prospects. Enclosure 1 to State Department Airgram A-051, Apr. 3, 1974, 2 pp.

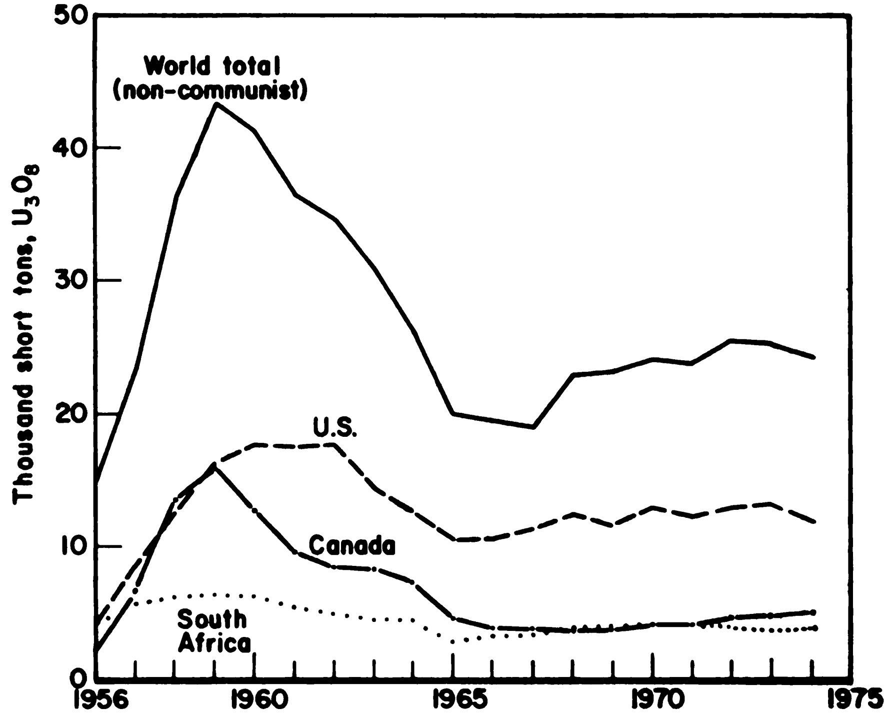

Figure 3.—World production of uranium concentrate (U_3O_8).

This does not include deposits in the Northern Territory and South Australia which have not been completely evaluated, particularly the Koongara deposit of Noranda Australia Inc., which is expected to be sizable.

In November the Prime Minister issued guidelines for Government control of and foreign participation in Australia's mineral industry, including uranium.[21] The uranium policy specified Government ownership of deposits and Government-industry partnerships in the Northern Territory; the Australian Atomic Energy Commission (AAEC), as the Government agent, would undertake all new exploration in the Northern Territory; a Government-sponsored mill in the Northern Territory; no new foreign participation; and AAEC-negotiated export contracts.

The Government planned to honor existing contracts for delivery of uranium. In August the Government agreed to underwrite a $30 million share issue by Mary Kathleen Uranium Ltd. for rehabilitating and reopening the Mary Kathleen mine in Queensland. Production was scheduled for 1976 at a rate of 1,000 tons U_3O_8 per year to fulfill contracts for approximately 5,200 tons U_3O_8. A total of 9,000 tons U_3O_8 will be delivered to Japan during 1976–86.

AAEC anticipated little demand for uranium in Australia before 1985, a cumulative demand of 30,000 tons U_3O_8 at the end of the century, and a total demand of 45,000 tons U_3O_8 to fuel planned reactors beyond 2000.[22]

Brazil.—Uranium reserves were small, but plans were made for an expanded exploration program. For 1974 $10 million was budgeted for exploration; for 1975 the budget will be doubled to $20 million. Reserves at a maximum of $15 per pound U_3O_8 were approximately 12,000 tons U_3O_8 at Cercado and Agostinho, near Poços de Caldas, State of Minas Gerais, and at Figueira, State of Paraná.[33] A pilot mill was in operation near the Cercado and Agostinho deposits late in the year.

---

[21] U.S. Embassy, Canberra, Australia. Prime Minister's Guidelines on Foreign Investment in Mining. Enclosure 1 to State Department Airgram A-212, Nov. 15, 1974, 1 p.

[22] Australian Atomic Energy Commission. Twenty-second Annual Report, 1973–74. Canberra, Australia, Aug. 23, 1974, 115 pp.

The Comissão Nacional de Energia Nuclear (CNEN) and its subsidiary for technology, Cia. Brasileira de Technologia Nuclear (CBTN), announced a large investment in nuclear research and development, uranium enrichment, and commercial reactor construction. A research and development budget totaling $570 million was proposed for 1975–80. CNEN planned for eight 1,200-megawatt reactors by 1990.

Canada.—Uranium production was slightly lower than that of 1973, owing chiefly to a production loss by Denison Mines, Ltd. at its Elliot Lake mine, Ontario. This loss was attributed to labor problems and the mining of lower grade ores.[34] Production continued at three operations—Rio Algom Mines Ltd., at Elliot Lake, and Eldorado Nuclear Ltd., in northern Saskatchewan, in addition to the Denison operation.

There were indications of renewed interest in uranium exploration following several years of little activity and a near standstill in 1973. This trend toward increased exploration was spurred by rising uranium prices and a developing seller's market. In addition to the provinces of Ontario and Saskatchewan, where activity was more extensive, prospecting and exploration for uranium were underway in virtually all other provinces.

In view of increasing foreign interest in purchasing Canadian uranium, the three operating mines and mills were undergoing expansion, and new operations were planned or under development. At Elliot Lake, Ontario, Denison Mines was increasing mine capacity by modifying its hoisting system and developing new ore. Mine capacity was being expanded to 10,000 tons of ore per day, and mill capacity to 7,100 tons per day. The nearby Stanrock mine, acquired through a merger, may be reopened and provide underground access to adjacent Denison properties.

Rio Algom Mines Ltd. operated its Quirke mill near full capacity of 4,500 tons per day. Mine expansion to 14,000 tons of ore per day and corresponding mill expansion (7,000 tons per day at the Quirke mill and 7,000 tons per day at the Nordic mill, which will be reactivated) were scheduled for 1980.

At Rabbit Lake, northern Saskatchewan, Gulf Minerals Canada Ltd. was stripping overburden for its open pit mine, and a 2,000-ton-per-day mill was near completion at yearend. Mining was scheduled for early 1975.

The Eldorado Nuclear Ltd. mill, also in northern Saskatchewan, was worked at only about 50% of capacity during 1974. Production was lower because one ore body was mined out. However, planned expansion will include new development, mine rehabilitation, and mill modernization.

Other prospective new operations included that of Agnew Lake Mines, Ltd. at Agnew Lake, Ontario, where a 2-year pilot plant, insitu leach project was planned for broken ores in stopes, and the Amok Ltd. Cluff Lake mine, northern Saskatchewan, which may be in operation by 1977.

A review of plans indicated that annual output of approximately 24 million pounds U_3O_8 may be anticipated before 1980.[35] It would be distributed as follows:

Company	Mine-mill location	Annual capacity (million pounds U_3O_8)
Rio Algom Mines Ltd.	Elliot Lake, Ontario	8.0
Denison Mines, Ltd.	do	6.0
Gulf Minerals Canada Ltd.	Rabbit Lake, Saskatchewan	4.5
Eldorado Nuclear Ltd.	Uranium City, Saskatchewan	2.5
Amok Ltd	Cluff Lake, Saskatchewan	2.0
Agnew Lake Mines, Ltd.	Agnew Lake, Saskatchewan	1.0
Total		24.0

[33] Engineering and Mining Journal. Brazil Launches Long-Range Program for Nuclear Development. V. 175, No. 12, December 1974, pp. 34, 39.

[34] Williams, R. M. Uranium: Shortage Hikes Prices. Can. Min. J., v. 69, No. 2, February 1975, pp. 130–135

[35] Nucleonics Week. V. 15, No. 24, June 13, 1974, p. 3.

The Government announced a new uranium export policy.[36] Effective September 5, 1974, it would provide for uranium sufficiency for domestic nuclear powerplants; a reappraisal of uranium resources up to a price of $30 per pound U_3O_8 by the Department of Energy, Mines, and Resources; export of uranium in the most advanced form, which is now UF_6 but may include enriched uranium and nuclear fuels in the future; a maximum contract period of 10 years, with possible 5-year extension; and a purchaser agreement not to reexport uranium acquired in Canada.

Annual uranium demand in Canada was about 550 tons U_3O_8 in 1974 and was expected to be 1,500 tons U_3O_8 in 1980. Committed nuclear capacity was 14,770 megawatts in 1974. Additional CANDU-type plants were planned at Pickering, Bruce, and Bowmanville in Ontario and at the Gentilly complex in Quebec. It was anticipated that by the year 2,000, 100,000 megawatts nuclear would be installed in Canada, and cumulative demand would be 150,000 tons U_3O_8.[37]

France.—During 1974 an ambitious nuclear power development program was announced as a means of reducing dependence on imported oil. Electricité de France (EdF), the national utility company, placed the largest nuclear reactor order to date—for twelve 900- to 1,000 Mw PWRs. The order was placed with Société Franco-Americain de Conservation Atomiques (Framatome), in which Westinghouse Electric Corp. is the reactor licensor and holds a 45% interest. EdF planned 50,000 Mw of nuclear capacity on line by 1985. The announced schedule called for the ordering of 6 units in 1974, 7 units in 1975, and 7 units per year from 1976 to 1980.[38]

Although Eurodif, the multinational uranium enrichment project, was advanced during 1974 with commitments to foreign participation and selection of a site in France, rising demand for enrichment services may necessitate purchases from the U.S.S.R., the extension of existing contracts with the United States, and purchases from the tripartite centrifuge enrichment project of the United Kingdom, the Netherlands, and West Germany.

France's prototype fast breeder, the 250-Mw Phénix, became the largest fast breeder operating at full nominal capacity. The next stage in fast breeder development is the 1,200-Mw Super Phénix, construction of which will be started in 1975. It will be owned by a multinational organization comprising French, Italian, and West German interests.

Germany, West.—In August the small uranium mill at Ellweiler resumed production after being idle for 1 year. A new mining license was granted to Gewerkschaft Brunhilde for the mining of 20,000 tons of ore by yearend 1974.

There were eight operable nuclear powerplants, and seven were under construction. The official Government plan called for 20,000 Mw nuclear capacity by 1980 and 45,000 to 50,000 Mw by 1985. Research and development continued on the second generation high-temperature gas-cooled (HTGR) and the fast breeder reactor at Kalkar.

Italy.—Production capacity of the mine at Novazzo, near Brescia, which is owned and operated by AGIP Mineraria, was 120 tons U_3O_8 per year. Reserves were 1,500 tons U_3O_8. A discovery in the Lazio area, near Viterbo, 50 miles north of Rome, reportedly contained 11,000 tons U_3O_8.

Japan.—Tokyo Uranium Development Corp., comprising five companies, was formed to promote the development of uranium deposits in Africa, Canada, Australia, and South America.

Japan will continue to rely on the United States for short-term enrichment services but was attempting to diversify its sources for these services. Early in the year, Japan agreed to purchase 1 to 1.5 million SWU per year during 1980–90 from the French-sponsored Eurodif project at a reported price of $57 per SWU. The U.S.S.R. may also provide enrichment services.

The Enrichment and Reprocessing Preparatory Group, comprising the Japan Atomic Power Co. and nine utility companies, will consider a large multinational project for uranium enrichment. The Government-controlled Power Reactor and Nuclear Fuel Development Corp. operated the first cascade under its gas centrifuge development program. A pilot plant was scheduled for 1978 and a commercial plant for 1 million SWU per year by 1985.

[36] U.S. Embassy, Ottawa, Canada. Canadian Uranium Policy. Enclosures 1–4 to State Department Airgram A-456, Sept. 10, 1974, 67 pp.

[37] Gilchrist, W. M. Future Uranium Needs a Challenge to Canada's Mining Industry. The Northern Miner, v. 59, No. 51, Mar. 7, 1974, pp. 37, 62.

[38] Nuclear Industry. Framatome in Line for Order of 12 PWRs for Early Construction. V. 21, No. 3, March 1974, p. 41.

Seven power reactors were in operation, and 15 were scheduled for completion during 1974–78. A new project, termed "the world's largest nuclear power center," would eventually reach 20,000 Mw in 20 plants along the north Pacific coast of Japan. Geological, climatic, and biological studies were underway on the environmental feasibility of a project of this magnitude.

Niger.—New exploration agreements were concluded. Continental Oil Co. and the French Commisariat'á l'Energie Atomique (CEA) started 3-year exploration venture on a CEA concession 50 miles south of the producing mine and mill at Arlit. Société des Mines du Djado was formed by CEA, the Government of Niger, and Urangesellschaft A.G. of West Germany to explore for uranium in the Djado region of northern Niger. In August, Japan's Power Reactor and Nuclear Fuel Development Corp. took a 25% interest in this venture.

Japan's Overseas Uranium Resources Development Co. joined with CEA and the Niger Government in Compagnie Miniére d'Akouta (COMINAK) in a mining and milling project west of Arlit. The mine will annually produce 650,000 tons of ore, which will be milled to about 2,400 tons U_3O_8.

South Africa, Republic of.—Uranium output, as a byproduct and coproduct at eight gold mines, was slightly lower than that of 1973. Production, in 1974, by mine, was as follows:

Mine	Pounds U_3O_8
Blyvooruitzicht	391,044
Buffelsfontein	1,609,857
Harmony	927,274
Hartebeestfontein	899,062
Vaal Reefs	1,954,279
West Driefontein	407,868
Western Deep Levels	300,375
West Rand Consolidated	288,164
Total	6,777,923

Thirteen gold mines were considered capable of supporting uranium production, and 11 mines had uranium extraction plants.

The South African Government held 20,000 tons U_3O_8 in stocks accumulated in excess of export sales contracts.

Because of anticipated growth in future demand for uranium, the Department of Mines started a comprehensive program evaluating uranium resources.

The enrichment pilot plant of the Government-owned Uranium Enrichment Corp. South Africa Ltd. (UEC) at Valindaba, near Pretoria, was near completion and was expected to be in operation in early 1975. UEC planned to proceed with construction of a large-scale commercial enrichment plant. Planning was in an advanced stage. Annual capacity of the plant will be 2.4 million SWU (2,645 tons of enriched uranium).[39]

In September plans were announced for a 2-unit reactor installation, each unit of 800- to 1,000-Mw capacity, at Koeberg, near Cape Town. A nuclear power program was proposed in order to preserve coal resources for the petrochemical industry for coal gasification and liquefaction.

South-West Africa, Territory of.—Open pit development and mill construction continued at the Rossing deposit. RTZ Corp. held the majority interest in Rossing Holding Co., the operating company. Rio Algom Mines Ltd. reportedly exercised an equity option for a 10% interest. The initial production rate will be 60,000 tons of ore per day and 15 million pounds U_3O_8 per year, making the mine the world's largest producer of uranium. The planned full production rate is 120,000 tons per day. Initial production was scheduled for late 1976 or early 1977.[40]

Sweden.—The Swedish Geological Survey was intensifying its search for uranium deposits. The Parliament approved an increase in the appropriation for uranium exploration to $2.2 million in fiscal 1975.

The low-grade Billingen shale in south-central Sweden, which is one of the world's largest uranium deposits in terms of U_3O_8 in ore, contains 0.03% U_3O_8 and 15% extractable hydrocarbons. The pilot mill at Ranstad (130 tons U_3O_8 per year), which remained inactive during 1974, may be enlarged to 1,300 tons U_3O_8 per year. This would necessitate the mining of 6 million tons of the shale per year.

United Kingdom.—After a year of uncertainty, a "White Paper on Nuclear Reactor Policy," released in July, announced a Government decision to proceed with nuclear power development based on the steam generating heavy water reactor (SGHWR) of U.K. design rather than the light water reactor of U.S. design.[41]

[40] Mining Journal. South-West Africa—New Political Pressure. V. 283, No. 7261, Oct. 18, 1974, p. 336.

Fuel was loaded in the 250-Mw Dounreay fast breeder in March, and testing was underway late in the year. This prototype will be the basis for the design of a commercial-scale, 1,300-Mw fast breeder reactor.

TECHNOLOGY

ERDA-sponsored projects on new exploration techniques included the development of small-diameter, pulsed neutron generators and probes for the direct measuring of uranium in boreholes and portable equipment for detecting and measuring radon and radon daughter products in water and soil gas. Model boreholes were prepared for the development and calibration of special probes measuring low-intensity gamma radiation. Research on remote sensing techniques was expected to enhance the Earth Resources Technology Satellite digital data for detecting significant geological features, such as rock types and rock alteration, related to uranium deposits.[42]

Other exploration techniques under investigation included measurement of thermal gradient to determine relative heat flux between sample points in shallow boreholes. A heat anomaly would indicate the possible presence of uranium ores.[43] Samples of helium or other inert gases, collected from soil in shallow boreholes, 3 to 10 feet deep, may be analyzed for abnormal concentrations, which may be indicative of hydrocarbons or radioactive ores. Samples were collected in a newly developed canister, having an open bottom and a closed top, in which the gas sample replaces air.[44]

Data-processing techniques were applied in interpreting radon sample data from boreholes in an exploration area.[45] Moving averages and other statistical analysis permitted more consistent repeatable results.

A conceptual model was evolved for the major productive uranium districts and belts, giving exploration and geological criteria that may be useful guides to new uranium districts. In developing the model, geological similarities and variations were considered in the sandstone-type deposits.[46]

Rising demand and high uranium prices spurred investigations on the extraction and processing of low-grade and refractory ores. Renewed interest in insitu leaching, or solution mining, of uranium resulted in a number of new operational techniques. Hydraulic fracturing occurs when a fluid is pumped into an entry well until the pressure exceeds the resistance in the formation. Tensile fracturing is extended with continued pumping. Optimum physical conditions for uranium leach are based on knowledge of the fracture types and their orientation; the fluid pressure including shut-in pressure (when pumps are not working); geology of the area; and the mechanical, physical, and chemical properties of the formation, mainly porosity and permeability. Fracturing properties would determine the path of fluid flow and the well location and spacing.[47]

Blasting may also be used to prepare a uranium ore body for a leaching operation. Fracturing with equal displacement and uniform fragmentation is desirable. Downhole and tunnel blasting have been tested; the more suitable method would depend upon the properties of the ore body. The Bureau of Mines was working on a fragmentation technique. Initial research was on a porphyry copper deposit, but many factors would also be applicable to other mineral deposits, including uranium.

[47] Engineering and Mining Journal. Solution Mining Opening New Reserves. V. 175, No. 7, July 1974, pp. 62–71.

Other leaching techniques under investigation included the addition of soluble aluminum sulfate, which limits the reduction in permeability of the deposit, thereby improving leach efficiency, and contacting the leach solution at depth with oxygen under pressure. The latter would convert the tetravalent uranium ion to the more readily soluble hexavalent ion.[48]

Several methods were employed to improve efficiency in heap, vat, or batch leaching operations. The ore may be agitated and dried to increase permeability or may be suspended in the leach solution and then treated with sodium chlorate and a polymer to. inhibit settling. Countercurrent leaching also may be useful, the leachant circulating upward through the ore descending from a feed inlet.

The Bureau of Mines initiated a project testing insitu leaching methods and costs. This project included a computer simulation program and the development of mathematical models for a pilot plant operation. A cooperative agreement was concluded with industry for a test site in the Red Desert, Wyo.

A borehole hydraulic mining method was developed for use in small, low-grade uranium deposits.[49] A capsule with a high-pressure water sinking jet, a flushing jet, and a hydraulically driven positive displacement pump is lowered into a service hole drilled 6 feet below the mining zone. The jet is rotated during operations. A mining rate of 40 tons of ore per hour was achieved with a jet pressure of 500 to 700 pounds per square inch.

Improved calibration procedures have been developed with new equipment for measuring and interpreting radon and its daughter products in underground uranium mines.[50]

A newly designed slide rule was developed for fast and accurate radon-daughter computations.[51] This instrument replaces tables, nomographs, and manual methods and minimizes the chance for mechanical or mathematical errors.

Numerous materials, including polyesters, resins, epoxies, lattices, and inorganic coatings, were tested in Bureau of Mines laboratories as sealants against radon gas in uranium mine walls. These materials could seal off up to 100% of the radon and were designed to be used in the main mine workings carrying fresh air to working areas. Field tests were planned.[52] For more efficient radon control, mine vent design and ore handling methods should receive increased attention during mine planning and development.[53] Methods to reduce radon contamination were described.

In Japan plans were made to use the heat from nuclear powerplant discharge water for recovery of uranium from seawater.[54] A newly developed absorber was a composite of active carbon and metallic bases of titanium and zinc. Two pilot plants will be built at coastal sites. It was estimated that uranium would be recoverable at a cost of $50 to $60 per pound U_3O_8.

The Bureau of Mines expanded its research and development work on processing technology for recovery of uranium from low-grade and refractory ores. Carboniferous ores resistant to conventional acid leach, were subjected to preliminary roast and flotation concentration to improve leachability. Low-grade resources under study included the Chattanooga shale, reduced to minus 3-mesh and subjected to stage leaching, samples from Wyoming and California containing 0.02% to 0.04% U_3O_8, and a flyash sample from a coal-fired powerplant, assaying 0.001% to 0.003% U_3O_8.

A strong (6*N*) sulfuric acid leach provided uranium recovery from refractory ore on a laboratory scale.[55] Strong acid leaching minimizes crushing and grinding costs, provides less effluent, provides savings in acid and water consumption, and requires only 20% to 25% of the leaching time for conventional processing.

The precipitation of uranium by hydrogen peroxide provided a better quality concentrate than that from precipitation with ammonia. Variable tests were made with hydrogen peroxide precipitant; initial and reaction pH, temperature and time, and content of vanadium, molybdenum, and sulfate, which are common yellowcake impurities.[56]

Solar heat will be employed to heat mill water to 140° F at a uranium mine and mill under development in New Mexico. The water will be heated in solar ponds, 2 inches deep and covering 6 acres. The ponds will have black bottoms for heat absorption and plastic covers.[57]

An electrolytic reduction process for refining and conversion to UF_4 at the mine site, bypassing the intermediate yellowcake stage, was reported in Japan.[58] The process involves high-efficiency cation exchange membranes and platinum-plated electrodes in an aqueous solution at room temperatures. The ore is leached in a UO_2SO_4 solution, which goes to mixer-settlers where an amine (in kerosine) extracts uranium as a sulfate complex. This is converted to uranyl chloride, which is reduced electrolytically to uranous chloride. A reaction with hydrofluoric acid forms UF_4.

Progress was reported in isotopic enrichment of U_{235} by the laser beam in the laboratory.[59] In one of a number of laser-related approaches to enrichment, the isotopic separation depends on the spectroscopic structures of molecules. In ERDA-sponsored research, a stream of hot atomic uranium gas was passed through a carefully tuned laser beam and intense ultraviolet light of an arc lamp. The laser selectively excited the electrons of the U_{235} isotope to an energy level enabling the ultraviolet light to ionize the atoms. The U_{235} isotopes acquired a net plus charge and were attracted to a negative charge collector. A high level of enrichment appeared attainable from a single pass through the laser device. Therefore, fewer enrichment stages would be needed and capital costs and power consumption would be substantially lower than from gaseous diffusion or gas centrifuge enrichment. However, for a commercial operation it would be necessary to scale up the laser energy one thousandfold.

Second generation gas-centrifuge models for isotopic enrichment were under reliability testing by ERDA. First generation models had undergone testing for 2 years. Advanced third generation models were through the initial design stage, and prototypes were undergoing testing.[60]

Another enrichment technique, the jet nozzle, was advanced by research in West Germany. A gas stream of 5 mole-percent UF_6 and 95 mole-percent helium or hydrogen was compressed through nozzles and directed toward a curved deflection wall, the heavier U_{238} isotopes following the outer paths. Energy consumption was high in this method.[61]

ERDA continued its basic research and development program on four breeder concepts—the liquid metal, fast breeder reactor (LMFBR), the light water breeder, the gas-cooled breeder, and the molten salt breeder. Reference designs, work schedules, and cost data were established for the demonstration Clinch River LMFBR in Tennessee. The Fast Flux Test Facility for testing breeder fuels and materials, and for safety and reactor development experience, was 40% completed at yearend. Progress was made in studies on advanced oxide fuels and higher breeding mixed uranium-plutonium carbide and nitride fuels.

Increased attention was given worldwide to the industrial use of reactor process heat.[62] In Japan research and design work on utilization of process heat were conducted on large, very high temperature, gas-cooled reactors. In West Germany, the emphasis was on process heat for coal gasification and liquefaction and the separation of hydrogen and oxygen from water. Steelmaking with reactor process heat, which would employ hot reducing gas in a direct-reduction process, combines the high temperature gas-cooled reactor, a catalytic steam reformer for converting fuel into a suitable reducing gas, a direct-reduction furnace for sponge iron, and an electric arc furnace. A technical obstacle was radiation safety in the heat exchanging mechanism.

[62] The Atom. Nuclear Heat for Industry—A Coming Revolution? V. 11, No. 6, November-December 1974, pp. 16–18.

In radioactive waste management, a new process, called the VR–20, was developed for treating low-level wastes.[63] Air is the fluidizing medium in this fluidized-bed calcination process. Water and air were driven off, leaving the solids in granular particles, which were formed into a solid mass by adding a thermosetting resin. The waste product for transportation would be homogeneous, water-free, and virtually unleachable.

Another proposal was made for disposal of high-level radioactive wastes in geological formations. This would be beneath mesas and plateaus in the arid and semiarid western and southwestern United States. The wastes, fused to glass of low solubility, would be placed in sealed containers, which would be stored in boreholes 50 to 100 feet below the surface.[64]

ERDA was studying three engineering concepts for retrievable surface storage—in water, in air-cooled vaults, and in surface casks. A pilot plant for testing disposal in geological formations was planned. Concerning transport of radioactive waste materials, package performance tests were made on the definition and evaluation of stresses that may result from accidents during air, rail, and highway transport. Casks as large as 25 tons will be tested.[65]

Vanadium

By Grace N. Broderick [1]

Consumption of vanadium in the United States continued to increase, reaching an alltime high of 7,200 short tons in 1974. The vanadium ore of Arkansas remained, as in 1973, the principal domestic source of supply. For the first time since 1968, domestic production of vanadium pentoxide increased. Exports of both ferrovanadium and vanadium ores, concentrates, and oxides declined in 1974. Imports of ferrovanadium and of residues and slags also were down from those of the previous year. U.S. price quotations for the principal vanadium materials, which remained stable in 1973, rose appreciably in 1974.

Table 1.—Salient vanadium statistics
(Short tons of contained vanadium)

	1970	1971	1972	1973	1974
United States:					
Production:					
Ore and concentrate:					
Recoverable vanadium [1]	5,319	5,252	4,887	4,377	4,870
Value ---- thousands	$34,923	$37,690	$30,867	$26,611	$38,266
Vanadium pentoxide recovered	5,594	5,293	5,248	4,864	5,368
Consumption	5,134	4,802	5,227	6,393	7,200
Exports:					
Ferrovanadium and other vanadium alloying materials (gross weight)	2,155	676	269	1,416	1,335

r Revised.

[1] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

Legislation and Government Programs.—There were no sales of vanadium in 1974 from the U.S. Government stockpile. The physical inventory, as of December 31, 1974, totaled 639 tons of vanadium, all of which was in the national stockpile. Of this total, 55 tons was contained in ferrovanadium, and 584 tons was contained in vanadium pentoxide. The ferrovanadium and 44 tons of the pentoxide had been sold previously and were awaiting shipment out of the Government stockpile. This left an uncommitted inventory of 540 tons of vanadium pentoxide, which cannot be sold until Congressional authorization is obtained.

DOMESTIC PRODUCTION

The principal domestic source of vanadium in 1974 continued to be the vanadium ore of Arkansas. The amount of vanadium recovered from Colorado Plateau uranium-vanadium ores increased, but that from Idaho ferrophosphorous declined. Some mills also processed vanadium-bearing oil residues, spent catalysts, and foreign vanadium-containing slags. Vanadium obtained by processing imported vanadium-containing slags was not included in any of the production figures shown in the tables nor was the vanadium recovered directly from slags or residues as ferrovanadium or similar products.

---

[1] Physical scientist, Division of Ferrous Metals.

Union Carbide Corp. continued to operate both its Uravan-Rifle mill complex in Colorado, and its Hot Springs, Ark., mill, while Kerr-McKee Corp. continued to recover vanadium from ferrophosphorous at Soda Springs, Idaho. Susquehanna-Western, Inc., sold its ore milling and processing facility at Edgemont, S. Dak., to the Tennessee Valley Authority (TVA) in August, and the plant was shut down. TVA planned to refurbish and enlarge the milling facilities, but actual commitment to final plans would depend upon completion and approval of an environmental impact statement.

Atlas Corp. proceeded with installation of a vanadium recovery circuit at its Moab, Utah, mill. The company continued to develop and mine some of the uranium-vanadium ore discovered in 1972.

Under the management of its Minerals & Chemicals Div., Engelhard Minerals & Chemicals Corp. began production of ferrovanadium in January 1974 at its new Strasburg, Va., plant, which has an annual capacity of about 1,000 tons of contained vanadium. Philipp Brothers, another division of Engelhard Minerals & Chemicals Corp., was responsible for the feed material and sales of the production.

Geo Industries, Inc., started shipping uranium-vanadium ore from its Geo No. 1 mine at Wray Mesa, Colo., to the Uravan mill of Union Carbide Corp.

Table 2.—Mine production and recoverable vanadium of domestic origin produced in the United States

(Short tons of contained vanadium)

Year	Mine production [1]	Recoverable vanadium [2]
1970	5,793	5,319
1971	5,547	5,252
1972	4,699	4,887
1973	4,117	4,377
1974	5,240	4,870

[1] Measured by receipts of uranium and vanadium ores and concentrates at mills, vanadium content.

[2] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

Table 3.—Production of vanadium pentoxide in the United States [1]

(Short tons)

Year	Gross weight	V_2O_5 content
1970	11,035	9,986
1971	10,492	9,448
1972	10,410	9,367
1973 [2]	8,226	8,683
1974 [2]	9,304	9,583

[1] Includes vanadium pentoxide and metavanadate produced directly from all domestic sources, plus small byproduct quantities from imported chromium ores in 1971 and the preceding years.

[2] V_2O_5 content exceeds gross weight because it includes considerable V_2O_4.

CONSUMPTION AND USES

Domestic consumption of vanadium, reported by type of material in table 4 and by end use category in table 5, rose about 13% in 1974 to reach an alltime high of 7,200 short tons. Increases occurred in all end-use categories except electric steel, tool steel, cast irons, cutting and wear resistant materials, welding and alloy hard-facing rods and materials, and pigments. Only in November did consumption drop below the rate of 500 or more tons per month. Eighty-seven percent of the vanadium was consumed as ferrovanadium and associated proprietary vanadium-iron-carbon materials. This represents the third consecutive year of increased consumption for these alloying elements.

The Vanadium International Technical Committee (Vanitec), formed in 1973 to promote greater use of vanadium, has progressed well. Its main efforts were directed in 1974 towards the development of line pipe steels for oil and gas transmission lines.

Table 4.—Consumption and consumer stocks of vanadium materials in the United States
(Short tons of contained vanadium)

Type of material	1973 Consumption	1973 Ending stocks	1974 Consumption	1974 Ending stocks
Ferrovanadium[1]	5,600	1,135	6,076	1,732
Oxide	199	49	218	83
Ammonium metavanadate	45	9	41	6
Other[2]	549	98	865	163
Total	6,393	1,291	7,200	1,984

[1] Includes other vanadium-iron-carbon alloys.

[2] Consists principally of vanadium-aluminum alloy, plus relatively small quantities of other vanadium alloys and vanadium metal.

Table 5.—Consumption of vanadium in the United States, by end use
(Short tons of contained vanadium)

End use	1974
Steel:	
Carbon	900
Stainless and heat resisting	38
Full alloy	1,744
High-strength, low-alloy	2,398
Electric	W
Tool	936
Cast irons	52
Superalloys	55
Alloys (excluding steels and superalloys):	
Cutting and wear resistant materials	W
Welding and alloy hard-facing rods and materials	10
Nonferrous alloys	722
Other alloys[1]	W
Chemical and ceramic uses:	
Catalysts	255
Other[2]	W
Miscellaneous and unspecified	90
Total	7,200

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified."

[1] Includes magnetic alloys.

[2] Includes pigments.

STOCKS

In addition to the consumers' stocks shown in table 4, producers' stocks of vanadium as fused oxide, precipitated oxide, metavanadate, metal, alloys, and chemicals totaled 1,920 short tons of contained vanadium at yearend 1974, compared with 2,815 short tons at yearend 1973.

PRICES

Prices in the United States for the principal vanadium materials, which were stable throughout 1973, moved upward during 1974 following the decontrol of ferroalloy prices in March.

The price for domestic 98% fused vanadium pentoxide, as quoted by Metals Week, which had remained at $1.50 per pound of contained V_2O_5 in 1973, increased to $1.75 effective March 1 and to $1.90 effective July 1. As of August 1, this became a dual quote of $1.90 to $2.72 per pound of contained V_2O_5. Effective October 1, Kerr-McGee Corp. raised its price 25 cents to $2.15 per pound of contained V_2O_5 and later raised it as of December 1 to $2.45. Union Carbide Corp. increased its price from $2.72 to $3.06 effective November 1.

The price for technical-grade, air-dried vanadium pentoxide, which at the beginning of the year was $2.21 per pound of contained V_2O_5, f.o.b. plant, was increased to $2.41 effective June 1 and to $2.72 effective August 1. As of November 1, the price quotation was $2.98-$3.06.

A price quotation for dealer-export merchant technical-grade vanadium pentoxide, which had been $1.50 per pound of contained V_2O_5 since July 1971, was no longer published by Metals Week after January 1974.

The price for U.S. standard grade ferrovanadium, which began the year at $4.19 per pound of contained vanadium, f.o.b. shipping plant, was increased to $4.62 effective June 1, to $5.21 effective August 1, and to $6.35 effective November 1. Foote Mineral Co., effective May 1, raised the price of its Ferovan to $3.96 per pound of contained vanadium, effective July 1 to $4.50, and effective November 1 to $5.10. Union Carbide Corp., effective June 1, raised the price of Carvan to $3.99 per pound of contained vanadium, effective July 1 to $4.50, and effective November 1 to $5.10. Carvan began the year at $3.66 per pound of contained vanadium and Ferovan at $3.68 per pound of contained vanadium.

FOREIGN TRADE

Exports of both ferrovanadium and vanadium ores, concentrates, and oxides were down from the previous year. The decreases in ferrovanadium and vanadium exports were about 6% and 13%, respectively. The average declared value for exports of ores, concentrates, and technical-grade oxides was $1.83 per pound of contained vanadium pentoxide in 1974, compared with $1.40 per pound in 1973. The average declared value for exports of ferrovanadium in 1974 was $2.94 per pound of alloy, compared with $3.08 in 1973.

No imports classified as vanadium ore and concentrate were received in 1974. Since January 1, 1974, imports of vanadium-bearing residues, such as ashes and slags, have been reported separately from other metal-bearing residues. They totaled 4.3 million pounds of contained vanadium in 1974. Most of this material came from the Republic of South Africa (51%), the U.S.S.R. (20%), and Chile (15%).

Imports of vanadium pentoxide, which hitherto have been of little consequence, totaled 1,904,182 pounds valued at $2,931,329 in 1974. These imports came from the Republic of South Africa, 1,738,628 pounds; Mozambique, 61,218 pounds; Finland, 60,075 pounds; West Germany, 44,259 pounds; and the United Kingdom, 2 pounds.

Ferrovanadium imports, which declined in quantity and value for the second consecutive year, are shown in table 7.

WORLD REVIEW

In addition to the nations listed in table 8, some others had relatively small vanadium production from secondary, waste, or byproduct sources. Japan and West Germany produced vanadium from several such sources.

Pipeline production was a major factor in demand for vanadium outside the United States in 1974. West Germany and Japan continued to be the largest consumers among the market economy countries.

Australia.—Foreign participation in Agnew Clough Ltd.'s vanadium project near Wundowie, about 47 miles northwest of Perth, Western Australia, was approved by the Australian Government. British Oxygen Ltd. and Mitsui and Co., Ltd. each held a 20% interest in the project and would guarantee markets for the vanadium. Site preparation would start in 1975, with the pelletizing, roasting, and leaching plant scheduled to come onstream toward the end of 1976 or early 1977.[2]

Bolivia.—Skoda Export, a Czechoslovakian company, began a feasibility study for a ferroalloy plant expected to be located near the city of La Paz. The plant would have a planned annual output capacity of 330 tons of ferrovanadium and 550 tons of ferrotungsten. Date for the start of its operation was tentatively scheduled for January 1977.[3]

Canada.—Vanadium oxides were not produced in Canada in 1974; Masterloy Products Ltd. suspended its production of vanadium pentoxide in June 1973. The company was having difficulty obtaining sodium fluorovanadate from the Aluminum Co. of Canada, Ltd. (ALCAN), which found it uneconomical to recover sodium fluorovanadate from its bauxite leaching circuit at Arvida, Quebec. Masterloy attempted to use fly ash from thermal power stations as a raw material, but this proved unsuccessful because of the inconsistency of the feed material. Masterloy still produced ferrovanadium by the aluminothermic process.

Chile.—Compañía de Acero del Pacífico was expanding steel capacity at its Huachipato plant, the source of Chile's vanadium-bearing slag, by 67%. The expansion would raise plant capacity to 1,102,310 tons of slag per year and was planned for completion by 1976.[4]

Finland.—According to Finnish trade statistics, Finland exported 2,594 tons of vanadium compounds[5] in 1973, of which 892 tons went to West Germany, 496 tons to Sweden, 443 tons to France, 331 tons to the U.S.S.R., and the balance to other European nations.

Rautaruukki Oy reported[6] that a new production record was achieved in the quantity of vanadium pentoxide produced at Otanmäki. Output increased by 18% from 2,248 tons in 1973 to 2,647 tons in 1974. The company completed planning of the process and plant for the Mustavaara mine during 1973, and construction was started in 1974. Mining would be by open pit methods with production scheduled to begin in 1976. The main product of this operation would be vanadium pentoxide, with the plant designed to produce 3,000 tons per year.

Germany, West.—According to official trade statistics, West Germany imported 32,848 tons (gross weight) of vanadium-containing ashes, residues, and slag in 1974, compared with 33,644 tons in 1978.

India.—The Geological Survey of India analyzed samples from a titanomagnetite deposit in the Chennagiri Taluk of Shimoga District, Karnataka State, and found that they ranged from 0.43% to 0.76% vanadium. Earlier work on a bulk sample of titanomagnetite ore from Devaranarasipur, near Bhadravati in Shimoga District, showed a content of 0.50% vanadium.

South Africa, Republic of.—Production of vanadium-bearing slag by Highveld Steel and Vanadium Corp., Ltd.,[7] totaled 38,053 tons (gross weight) in the fiscal year ending June 30, 1974, compared with 37,560 tons in the previous fiscal year. Fused vanadium pentoxide production from the company's Vantra Division was reduced during fiscal year 1974, due to an oversupply position, particularly in Europe. Since the suspension in 1972 of mining operations by Transvaal Vanadium Co. (Pty.) Ltd., a wholly-owned subsidiary of Highveld, at its Kennedy's Vale mine, Lydenburg district, ore for the Vantra Division has been supplied by Highveld's own Mapochs mine, situated near the village of Roosenekal in the Middelburg district, Transvaal.

[7] Highveld Steel and Vanadium Corp., Ltd. Interim Report for the Half Year Ended 31st December 1974. Witbank, Feb. 4, 1975.

The R14 million expansion plan of Highveld Steel and Vanadium Corp., Ltd., mentioned in last year's chapter, has progressed well. The company hoped to commission the fifth furnace and sixth kiln in the iron plant early in 1975, and in the steel plant, the fourth continuous casting machine was expected to be commissioned in the middle of 1975.[8]

The vanadium pentoxide plant of Transvaal Alloys Ltd., a joint venture of the Otavi mining group and Vereinigte Aluminium-Werke A.G. of West Germany, began production in July.[9] The plant, which will mainly supply Japan, is located near Stoffberg and has a product capacity of 840 tons of contained vanadium. Vanadium for the plant is from a titaniferous magnetite deposit near Uitvlugt, Transvaal.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Based on reported United States imports from Chile.

[2] Content of vanadic acid derived from bauxite.

[3] Available sources suggest that production was terminated during 1970, but no production figures for that year were released.

[4] Revised to zero on the basis of sources indicating that production was terminated during 1970.

[5] The Republic of South Africa officially reported the production of vanadium in pentoxide and vanadate products for 1969–71, and an undistributed total production for 1972–74. Data on vanadium content of slag for all years in this table have been estimated on the basis of a reported tonnage of vanadium-bearing slag (on a gross weight basis) multiplied by an assumed grade of 14% vanadium in the slag. Thus, output of vanadium in slag as well as total vanadium output figures for 1969–71 are estimated (as the result of adding an estimate for vanadium in slag to a reported figure for vanadium in pentoxide and vanadate products). Similarly, the distribution of total production of contained vanadium between the content of pentoxide and vanadate products and the content of slag are estimates derived by subtracting the estimated content of slag from the reported total vanadium output.

[6] Series revised to reflect reported output of South West Africa Co. Ltd. for years ending June 30 of that stated.

TECHNOLOGY

A process for extracting vanadium from weathered shale containing about 1% V_2O_5 was developed on a laboratory scale by the Bureau of Mines. Testing was done using shales from a deposit near Carlin, Nev., and an extraction of 69% was achieved. The vanadium-bearing beds in this area are part of the Woodruff Formation of Devonian age. Two distinct types of shale, which differed in response to metallurgical treatment, were studied: Dark-brown carbonaceous or unweathered shale containing about 10% organic carbon, and gray-weathered shale containing less than 1% of organic carbon. The process consists essentially of salt roasting, leaching with dilute sulfuric acid, solvent extraction, and precipitation of vanadium as ammonium metavanadate. The carbonaceous unweathered shale was less amenable to treatment.[10]

Experimental work was conducted on the coreduction of titanium, aluminum, and vanadium chlorides by the Kroll (magnesium reduction) process to produce a homogeneous titanium alloy sponge. The yields of sponge were comparable with those of pure titanium sponge made in the same reactor. When VCl_4 in solution in $TiCl_4$ was fed into the molten magnesium, the vanadium concentration was very uniform throughout the sponge cake. More difficulty was encountered when feeding solid VCl_2 and $AlCl_3$. Vanadium and aluminum concentration in the sponge was not uniform, and mechanical difficulties were experienced with the small-scale screw feeder. Although the composition varied in various regions of the sponge cake, the ingots prepared from it were uniform in composition.[11]

The experimental technique developed by the Bureau of Mines for measuring the rate of electrochemical reaction between reactive metal electrodes and molten salt electrolytes containing multivalent ions was applied to the vanadium metal-vanadium subchloride system. The rate was found to be dependent on current density and VCl_3 concentration but almost independent of VCl_2 concentration.[12]

Samples of Devonian, Silurian, and Ordovician crude oils from Illinois were analyzed by neutron activation analysis for their vanadium content.[13] Concentrations, which ranged from 0.03 to 3.72 micrograms per milliliter, were low in crudes that came from reservoirs that were greater than 3,200 feet in depth. Maps of vanadium concentrations in these crudes appear to reflect structural features, such as the Sparta Shelf and the Sangamon Arch.

The electrolytic hydrogen evolution reaction (HER) was studied on vanadium in sulfuric acid-sulfate solutions. Data include Tafel slope, exchange current density, apparent heat of activation, reaction order derivative, corrosion potential, corrosion current, and hydrogen adsorption in gas phase.[14]

Thin sections can be removed from vanadium metal by a combined anodizing and stripping technique. A uniform, thin oxide film can be grown on the vanadium metal in an acetone-benzoic acid-sodium tetraborate solution during anodization, followed by stripping of the resulting oxide film in an aqueous solution of 10% NH_4OH. The section thickness varies linearly with the applied voltage across the cell. This technique can be applied for constructing penetration profiles in diffusion studies.[15]

A study on the solid-solubility limit of nitrogen in vanadium covering the temperature range 500° to 1,500° C and using several different techniques was carried out.[16] It is part of more extended ongoing investigations concerned with transformation and precipitation processes in the system vanadium-nitrogen.

Vermiculite

By Frank B. Fulkerson [1]

Crude vermiculite output totaled 341,000 short tons in 1974, a decline of 7% from the record 365,000 short tons produced in 1973. Crude vermiculite, mined and milled in Montana and South Carolina, was shipped to 53 exfoliating plants in 31 States for processing. Exfoliated vermiculite was used mainly in the building industry as concrete aggregate; as premixes for acoustic, fireproofing, and other purposes; and as loose fill and block insulation. Demand for the lightweight product was reported to be strong, despite a decline in building activity; however, owing to a decrease in supply of crude vermiculite, the quantity of exfoliated vermiculite sold or used by producers declined 6%.

Table 1.—Salient vermiculite statistics

	1970	1971	1972	1973	1974

World: Production, crude thousand short tons --	431	459	512	549	554

DOMESTIC PRODUCTION

Crude Vermiculite.—Output decreased from 365,000 short tons in 1973 to 341,000 short tons in 1974. Owing to startup problems at the new $7 million wet-processing plant of W. R. Grace & Co., Construction Products Division, at Libby, Mont., full operation was not expected until 1975. Ore reserves near Libby were reported to be sufficient for 50 years at the present rate of mining.[2] W. R. Grace & Co. also mined vermiculite near Enoree, S.C. In addition, Patterson Vermiculite Co. produced a small tonnage at Lanford, S.C. Plans of W. R. Grace & Co. to develop vermiculite deposits near Louisa, Va., were shelved as the result of zoning problems.

Exfoliated Vermiculite.—Several exfoliators reported they would have processed more crude vermiculite if it had been available. The tonnage of exfoliated vermiculite sold or used decreased from 293,000 in 1973 to 275,000 in 1974. Leading States, accounting for 46% of the exfoliated vermiculite sold or used, were, in alphabetical order, California, Florida, New Jersey, South Carolina, and Texas. W. R. Grace & Co., Construction Products Division, the principal producer of crude vermiculite, operated 28 exfoliating plants in 22 States. A quantity of crude vermiculite from the Republic of South Africa was exfoliated in the United States.

[2] W. R. Grace & Co. 1974 Annual Report. P. 15.

CONSUMPTION AND USES

The use pattern for exfoliated vermiculite by main categories was as follows: Aggregates, 52%; insulation, 29%; agriculture, 17%; and miscellaneous, 2%. End uses in 1973 and 1974 follow, in thousand tons:

Use	1973	1974
Aggregates:		
Concrete	88	94
Plaster	7	5
Premixes [1]	42	42
Total	137	141
Insulation:		
Loose fill	82	47
Block	9	32
Packing	1	1
Total	92	80
Agriculture:		
Horticulture and soil conditioning	40	40
Fertilizer carrier	9	7
Other	1	--
Total	50	47
Miscellaneous	14	6
Grand total	293	274

[1] Includes vermiculite used in premixes for acoustic and fireproofing purposes, decorative textures, moisture sealant, etc.

PRICES

According to the Bureau of Mines canvass, the average value of crude vermiculite was $29.68 per ton, compared with $25.93 in 1973, and the average value of exfoliated vermiculite was $112.42 per ton, compared with $106.44 in 1973. These values are f.o.b. mine or plant and exclude container cost where applicable.

The Engineering and Mining Journal quoted nominal yearend prices for crude vermiculite as follows: Per short ton, f.o.b. mine, domestic ore, $30 to $48; and c.i.f. Atlantic ports, the Republic of South Africa ore, $55 to $70.

FOREIGN TRADE

The Republic of South Africa was the only significant source of vermiculite imports. The crude vermiculite was imported duty-free into the United States. A quantity of crude ore was exported from the United States to Canada; however, tonnage figures were not published.

WORLD REVIEW

Canada.—Most of the crude vermiculite exfoliated in Canada was imported from Montana; some was imported from the Republic of South Africa. Grace Construction Materials Ltd. operated exfoliating plants at St. Thomas and Ajax, Ontario; Winnipeg, Manitoba; Regina, Saskatchewan; Edmonton, Alberta; and Vancouver, British Columbia. F. Hyde & Co., Ltd. and Vermiculite Insulating Ltd. operated exfoliating plants at Montreal and Lachine, Quebec, respectively. The use pattern in 1973 was loose insulation, 73%; insulating concrete, 7%; insulating plaster, 3%; and miscellaneous 17%.[3]

South Africa, Republic of.—Vermiculite ore produced in the Transvaal, Republic of South Africa, is exported through the Port of Lourenço Marques in Mozambique. Exports in 1974 declined because political unrest in Mozambique caused work stoppages at the port. There were long delays in berthing and loading ships. Many rail cars were also blocked because their freight could not be unloaded, and this resulted in a shortage of rail cars. By yearend, the flow of vermiculite shipments through the port had returned to normal.[4]

Zinc

By V. Anthony Cammarota, Jr.,[1] and Herbert R. Babitzke[1]

The slackening demand for zinc that began late in 1973 continued through 1974, principally as a result of the downturn in automobile production. Consumption of slab zinc decreased 14% from that of 1973 to 1,287,696 tons.

Mine production in 1974 was 499,872 tons, up 4% from that of 1973. New York, Missouri, and Tennessee were the principal producing States accounting for 54% of domestic production. Two new mines, one each in Tennessee and Utah, were developed for commercial production in 1975.

Smelter production of slab zinc from ore was 555,188 tons in 1974, a 5% decrease from that of 1973. This continued the declining trend that started in 1970. Two companies announced plans to erect two new electrolytic zinc smelters. Upon completion of the plants, possibly in 1977, domestic capacity will be increased by 340,000 tons annually to over 1 million tons. One plant is to be located at Clarkesville, Tenn., and the other at Stephensport, Ky. A new electrolytic zinc refinery is under construction at Bartlesville, Okla., to replace the horizontal zinc smelter. The Texas Air Control Board extended permission to operate the other remaining horizontal retort smelter until May 31, 1975, the date scheduled for closure.

Exports of slab zinc increased 31%. General imports of zinc in ores and concentrates increased 20% over those of 1973 to 240,043 tons, mainly through increased receipts from Canada. Imports for consumption of zinc ores and concentrates declined 13% to 133,733 tons. In 1974, both general imports and imports for consumption of slab zinc were nearly the same, at 539,538 tons and 543,806 tons, respectively, representing decreases of about 8% from those in 1973. Canada provided over half of the slab zinc imports, followed by Japan, Australia, Peru, and Belgium-Luxembourg.

The General Services Administration (GSA) continued to release zinc from the national stockpile as authorized by Public Law 92–283. On the first of January 412,385 tons of zinc were available for commercial disposal. Early in the year GSA started a new set-aside program by offering 150,000 tons over a period of 1 year with 75,000 tons available for the second quarter of 1974 and 25,000 tons each quarter thereafter. GSA sales of stockpile zinc in 1974 amounted to 264,325 tons, leaving a balance of 148,060 tons authorized for release.

Legislation to suspend the duty on imports of zinc concentrates was vetoed by the President because it contained a nongermane tax rider. The bill would have suspended through June 30, 1977, the 0.67 cents per pound import tariff on zinc ores, concentrates, and certain other zinc-bearing materials.

The monthly average price of domestic Prime Western zinc ranged from 31.2 cents per pound for January to 39.3 cents per pound for September. The yearend quoted price was 38 to 40 cents per pound, with the average for 1974 at 35.95 cents per pound. The London Metal Exchange (LME) price rose from 61.3 to 96.6 cents per pound from January to May, then declined sharply to the yearend quotation of 32 cents per pound.

Legislation and Government Programs.—GSA continued the sale of zinc from the stockpile during 1974. Commercial sales totaled 264,325 tons in 1974; 124,416 tons was sold under the set-aside program, and

---

[1] Physical scientist, Division of Nonferrous Metals.

139,909 tons was sold to the seven participating primary producers. Part of the zinc sold was from the 55,085 tons that remained from 1973 under authorization of Public Law 92–283. To that amount of zinc, Public Law 93–212 of December 28, 1973 added 357,300 tons for a total amount authorized of 412,385 tons. Based on inventories, zinc shipments from the stockpile in 1974 were 285,409 tons. This amount included shipments of zinc that had been sold to the Department of the Treasury in 1970. Government agencies also received an additional 1,592 tons of zinc leaving a balance of 20,388 tons for Government use as authorized by Public Law 89–9.

Under Public Law 93–212, 207,300 tons was to be released to primary domestic producers in continuation of their contracts and 150,000 tons was made available on the set-aside sales program for U.S. consumers. Four grades were made available as follows: High Grade, Intermediate, Brass Special, and Prime Western. The set-aside program offered 75,000 tons for the April through June period, and 25,000 tons for each of the following three quarters commencing with July 1974.

The price of the set-aside Prime Western, Intermediate, and Brass Special Grades was at the Metals Week monthly average quotation for domestic Prime Western zinc for the month following delivery. High Grade zinc was sold at the Metals Week average price for the month of delivery. All sales were f.o.b. storage location with a 0.75-cent-per-pound freight allowance. The price basis for producer contracts was the Metals Week average for the actual month of delivery. Additional allowances were permitted producers of secondary slab zinc, importers, and distributors and dealers of slab zinc as follows: For direct shipment, 0.45 cents per pound and for melting and recasting into slab zinc, 0.95 cents per pound.

The International Lead and Zinc Study Group held its eighteenth session in Geneva, Switzerland, November 13–18, 1974, to review developments in lead and zinc and consider projections for 1974 and 1975. The Group completed work on a special report on secondary lead and zinc and compiled a comprehensive list of new mine and smelter projects. The report showed that about one-fourth of world zinc consumption was supplied from secondary material.

DOMESTIC PRODUCTION

MINE PRODUCTION

Mine production in the United States was 499,872 tons of recoverable zinc, an increase of 4% over that of 1973. Significant increases were recorded for Missouri, New York, and Tennessee, but significant decreases were noted for Colorado, Idaho, Maine, and Utah. Nevada produced zinc for the first time since 1971. New York was the leading producing State in 1974 with 19% of the total production, followed by Missouri, 18%; Tennessee, 17%; and Colorado, 10%.

Sources of the zinc production for 1974 are shown in table 4 according to the class of ore in terms of recoverable metals. The distribution of zinc by various classes of ore is as follows: Zinc ore, 59%; zinc-lead ore, 15%; lead ore, 19%; copper-zinc and copper-lead-zinc ore, 4%; and other sources, 3%.

The 25 leading mines listed in table 5 accounted for 90% of the recoverable domestic zinc mined in 1974. The five leading mines produced 42% of the total and the first 10 mines produced 61%.

Zinc mine production in New York increased 14% over that of 1973, all of which came from the Balmat-Edwards mining complex of St. Joe Minerals Corp. The level of production of zinc in concentrates continued to improve. The Balmat mill serving the Balmat mine operated near its capacity of 4,300 tons per day. The Edwards mill treated ore from the Edwards mine. Total quantity of zinc concentrates produced in 1974 was 221,436 tons.[2] The Hyatt mine located between the Balmat and Edwards mines was reopened as a result of drilling that located zinc ore below existing workings in the old mine which had been abandoned about 20 years ago. It was reported that the Hyatt mine may replace production from the Edwards mine where deposits are expected to be depleted in 5 years. Limited production at the Hyatt mine began late in 1974 and exploration continued.

---

[2] St. Joe Minerals Corp. 1974 Annual Report. P. 16.

Zinc production in Missouri, up 12% from that of 1973, was derived wholly from eight lead mines. St. Joe Minerals Corp. lead mines in southeast Missouri (Fletcher, Viburnum Nos. 27, 28, and 29, and Brushy Creek) increased production of zinc in concentrates almost 100% over 1973 production. Brushy Creek operated at close to capacity during 1974 and played an important role in the improvement of production over 1973 levels.[3] The Missouri mine-mill-smelter complex, jointly owned by AMAX Inc. and Homestake Mining Co. produced 110,400 tons of zinc concentrates from the Buick mine in 1974. Production was down 6,100 tons when compared with that of 1973 because of slight decreases in ore grade.[4] The Magmont mine at Bixby, Mo., operated by Cominco American Incorporated, a joint venture of Cominco, Ltd. (50%) and Dresser Industries, Inc. (50%), produced 1,042,000 tons of ore at a combined lead-zinc grade of 8.2%.[5] Ozark Lead Co., a wholly-owned subsidiary of Kennecott Copper Corp., continued to produce zinc as a byproduct of lead.

Tennessee ranked third in domestic zinc mine production in 1974 with an increase of 34% over that of 1973. The New Jersey Zinc Co. continued exploration work near Carthage in central Tennessee. Mining commenced in 1974 at the Elmwood mine, although no production was reported, and the company completed construction of its new zinc mill. The mill has standard flotation cells, preceded by heavy media separation. The rated capacity of the concentrator is 3,500 tons per day of crude ore to produce a 63% zinc concentrate, aggregate stone, and limestone. The concentrate will be shipped by rail to the company smelter at Palmerton, Pa., until the new zinc plant at Clarksville, Tenn., is completed. The company announced that the deposit contained 20 million tons of zinc ore grading 4.5% to 5% zinc. By yearend 1974 about 25,000 feet of lateral development was completed. The company was also drilling a pilot hole for a new mine 2 miles southeast of the main shaft of the Elmwood mine. The New Jersey Zinc Co. began dewatering the Idol mine in east Tennessee, and additional underground exploration was scheduled. Plans were to do selective high-grade mining and to install a small mill for processing 4% to 4.5% zinc ore. The Flatgap mine will remain on standby, although the mill was dismantled and the equipment was installed at the Elmwood mill.

The Getty Oil Co. announced a 3-year, $2.3 million joint venture exploration project in Tennessee with Kinsho-Mataichi Corp., Dowa Mining Co., Ltd., Mitsubishi Metal Corp., and Mitsubishi Corp. Getty will control and direct the project and the Japanese companies will fund 80% of the cost. Occidental Minerals Corp. (Oxymin) increased its lease holdings near Carthage to 14,400 acres, and an agreement was made with a mining company to continue exploration and possible development of the project.[6] American Smelting and Refining Company (ASARCO) proceeded on schedule with construction of the Young mill which should be operational by mid-1975. The Young mill will have the capacity to treat increased output from ASARCO's Tennessee mines, which was 56,400 tons of zinc in 1974, nearly double that of 1973.[7] Cities Service Co. continued production of zinc concentrate at its Copperhill, Tenn., operations. Sales of concentrate decreased substantially to 6,400 tons, 65% less than those of 1973.[8]

Mine production in Colorado decreased 15% from that of 1973 to 49,489 tons. The Eagle mine of The New Jersey Zinc Co. was the leading zinc producer in the State. The Leadville mine (called Resurrection mine by Newmont Mining Corp.), a joint venture shared equally by Newmont and ASARCO was the second largest producer in the State. It produced 12,400 tons of zinc in 1974, a decrease of 15% compared with 1973 production.[9] Average zinc content of the ore milled was 9.6% zinc. Ore reserves were estimated at 2,655,000 tons averaging 9.4% zinc. The third largest zinc producer in Colorado was the Newmont Idarado mine. The Idarado mill treated 396,600 tons of ore averaging 3.33% zinc. Production increased 5% over that of 1973. Ore reserves were increased at the end of 1974 to 3,882,000 tons averaging 4.41% zinc.[10]

[10] Newmont Mining Corp. 1974 Annual Report. P. 6.

was 39,469 tons, a decrease of 14% from that of 1973. Increased development work resulted in higher confirmed ore reserves for the Bunker Hill and Star mines. In 1974, proven reserves at the Bunker Hill mine were increased to 2,493,600 tons of ore with a zinc content of 3.5%. Proven reserves at the Star mine were 624,000 tons of ore with a zinc content of 7.2%. The average grade of Bunker Hill reserves declined as a consequence of the addition of substantial low-grade reserves in the upper portion of the mine. Programs for increasing ore reserves through both internal and external exploration will continue over the next several years.[11]

The Hecla Mining Co. Lucky Friday mine produced 165,695 tons of silver ore assaying 1.18% zinc. Tonnage of ore mined decreased from that of 1974 due to a shortage of experienced underground miners. Development of the ore body at the 4,050-foot level was essentially completed and the tenor of ore corresponded favorably with that on the level above. The main shaft was deepened by 162 feet to reach below the 4,450-foot level.

Sunshine Mining Co. is the operator of the Sunshine unit area and mines the ore owned by Hecla, Sunshine, and Silver Dollar Mining Co. Development work on the 4,200- and 5,400-foot levels expanded the limits of two veins. The exposures were encouraging since they are situated along a previously unproductive structure. The tailings pond capacity was increased during the year, thus providing sufficient space for mill tailings for the next several years.[12] Day Mines, Inc., through an independent contractor, produced 22,118 tons of ore from the Monitor mine in 1974. The ore which averaged 4.58% zinc also contains silver and lead. Ore reserves were estimated to be adequate for approximately 1½ years of operation at the current rate of production.[13]

Production in New Jersey, Pennsylvania, and Virginia by The New Jersey Zinc Co. increased 3% over that of 1973. All the ore mined was milled near the mines and the concentrate was shipped to the company refinery at Palmerton Pa.[14]

Mine production at the Blue Hill mine in Maine decreased 47% from that of 1973 to 10,425 tons in 1974. During the year the mill treated 206,400 tons of ore with an average zinc content of 6.44%. Minable reserves at yearend were 701,000 tons of ore with a zinc content of 5.31%.[15]

Mine production in Utah declined to 12,619 tons in 1974, a decrease of 25% from that of 1973. Despite lower production of zinc, lead, and silver, the Tintic Division (Utah) of Kennecott Copper Corp. benefited in 1974 from higher metal prices. The mine continued to operate under adverse conditions including groundwater problems and high temperatures.[16] The Park City mine in Utah, developed as a joint venture between The Anaconda Company and ASARCO, will be ready for production in 1975.

Arizona zinc mine production totaled 9,699 tons in 1974, an increase of 15% over that of 1973. Cyprus Bruce Copper & Zinc Co. owned and operated the Bruce mine near Bagdad. Nearly 93,000 tons of ore was mined with an average grade of 3.86% copper and 13.6% zinc. Proven ore reserves totaled more than 300,000 tons with an average grade of 12.5% zinc and 3.74% copper. At the current mining rate, quantity of ore was adequate for 3 years of operation. Exploration was continuing.[17]

Mine output of zinc from New Mexico increased 12% in 1974 to 13,784 tons. At ASARCO's Ground Hog mine the zinc content of ore produced was 12,400 tons in 1974 compared with 13,500 tons in 1973. Major improvements at the mine included the installation of new trackless equipment which increased productivity and lowered costs.[18]

UV Industries, Inc., continued its exploration program to define additional copper ore in the Central district of New Mexico as well as to evaluate the potential recovery of iron and zinc. All the activity took place in Grant County at the Continental and Hanover mines.[19]

Mine production of zinc in Washington was 6,909 tons in 1974, an increase of 8% over that of 1973. In March, Gulf Resources & Chemical Corp. acquired Pend

Oreille Mines and Metals Co.[20] The Bunker Hill Co., a division of Gulf Resources, continued operation of the Pend Oreille mine. Surface drilling continued throughout 1974 at the Washington Zinc Unit of the Callahan Mining Corp. zinc-lead property near Colville, Wash. The program is being managed by Callahan and funded by United States Borax & Chemical Corp. and Brinco Ltd. The zone of known mineralization was increased substantially and an underground program to test the ore potential was underway.[21]

Wisconsin mine production of zinc was 8,737 tons in 1974, an increase of 1% over that of 1973. Production in southern Illinois declined 22% from that of 1973. Production in Kentucky ceased while Nevada, with 3,405 tons, produced zinc for the first time since 1971.

SMELTER AND REFINERY PRODUCTION

U.S. slab zinc production at seven primary plants and six secondary plants was 633,723 short tons in 1974, a decrease of 5% from that of 1973. The decrease may be attributed to the closure of a horizontal retort smelter at the end of 1973 and an overall decline in production. The AMAX electrolytic refinery at Sauget, Ill., more than doubled its production over that of 1973.

Producer stocks increased 10% during the year from 25,947 tons to 39,720 tons. In addition to slab zinc production, the seven participating primary domestic producers purchased 84,685 tons of GSA stockpile zinc during the year; 49,508 tons was shipped directly to their customers, and 35,177 tons was remelted.

Smelter and refinery capacities decreased by 19,000 tons. With the closure of AMAX's Blackwell, Okla., smelter and expansions at the Sauget, Ill., plant, industry capacity stood at 731,000 tons by yearend.

Slab zinc production at the smelter and electrolytic refineries was from domestic ore, 55%; foreign ore, 33%; and scrap, 12%. Zinc produced from foreign sources increased 13% over that of 1973 while that produced from domestic ore and scrap decreased 13% and 6%, respectively.

Primary slab zinc produced at electrolytic refineries increased 7% over that of 1973 and was 36% of the total slab zinc produced. Smelter production (distilled) was down 12% and made up 52% of the total. Redistilled slab zinc from secondary zinc materials at primary smelters decreased 17% and contributed 9% of the total, and redistilled slab zinc at secondary smelters increased 44% and was 3% of the total. Distribution of slab zinc production by grades was Prime Western, 48%; Special High Grade, 44%; Intermediate, 4%; High Grade, 3%; and Brass Special, 1%.

ASARCO proposed building a 180,000-ton-per-year electrolytic zinc plant at Stephensport, Ky., at an estimated cost of $160 million. A contract was awarded in October for design and engineering of the facility. Arrangements for an adequate supply of power were expected to be completed in 1975. The project could come onstream late in 1977. Construction began on a new 350-ton-per-day sulfuric acid plant at the ASARCO electrolytic zinc refinery in Corpus Christi, Tex., and should be completed in 2 years. The new acid plant will replace two existing plants dating back to 1942.

ASARCO's 50-year old, 50,000-ton-per-year horizontal retort smelter at Amarillo, Tex., operated under a Texas Air Control Board variance until May 31, 1975. The plant was scheduled for closing at that time. The ASARCO zinc fuming plant at East Helena, Mont., received extensive modernization in 1974, including construction of a new 350-foot stack to improve dispersion of filtered furnace gases.[22]

AMAX continued the rehabilitation and improvement program of the electrolytic zinc plant at Sauget, Ill. The addition of preleach facilities to process high magnesium-bearing concentrate from Missouri was completed in 1974. Other projects underway will facilitate expansion of production to 84,000 tons of zinc per year by 1976. All operations at the Blackwell, Okla., zinc plant ended in December 1974. The horizontal retort smelter was closed in 1973 but the sinter plant continued production until August 1974 and the cadmium plant continued until December 1974.[23]

St. Joe Minerals Corp., the largest domestic zinc producer, produced 223,968 tons of zinc (zinc equivalent) in 1974, 3% below 1973 production. The decline was due to continuing furnace problems and a slackening in zinc and zinc oxide demand in the fourth quarter which dictated a cutback in the rate of production.[24]

[20] Page 4 of work cited in footnote 11.

[21] Callahan Mining Corp. 1974 Annual Report Pp. 5–6.

[22] Pages 6 and 9 of work cited in footnote 7.

[23] Work cited in footnote 4.

The New Jersey Zinc Co. planned to construct an electrolytic zinc refinery near Clarksville, Tenn., with production scheduled to begin in 1977. This will be the first new zinc-producing facility to be built in the United States in over 30 years.[25] Projects were underway to increase zinc oxide capacity and improve processing techniques at the Palmerton, Pa., smelter. In addition, expenditures were made to comply with environmental requirements.[26]

The Bunker Hill Co. of Kellogg, Idaho, produced 92,000 tons of zinc in 1974, down from 98,000 tons in 1973. The rated annual capacity of the zinc plant was 109,000 tons. The decline in production during the year resulted from area flooding, interruptions in electrical supply, and a 10-day strike.[27]

On February 11, 1974, Engelhard Minerals & Chemical Corp. consummated the purchase of the assets of National Zinc Co., Inc., which was principally the zinc smelter at Bartlesville, Okla. The plant produced approximately 50,000 tons of zinc metal per year. The company was converting the existing horizontal retort smelter to an electrolytic facility at a cost of $40 million. The new plant was scheduled to be in production in 1976 and will be designed to comply with applicable pollution control laws.[28]

Secondary Zinc Smelters.—Zinc recovered from processing zinc-bearing scrap was 338,482 tons in 1974, a decrease of 12% from that of 1973. Semimanufactured forms and shapes of alloys, primarily zinc- and copper-base alloys, accounted for 98% of the new and old scrap processed. New scrap, chiefly zinc- and copper-base alloys from manufacturers and drosses from galvanizing kettles and diecasting pots accounted for 78% of all the scrap processed. The zinc was recovered in alloys, mostly in brass and bronze, 51%; as zinc-metal, 32%; and in chemical products, 17%.

Slag-Fuming Plants.—Slag fuming plants processed new hot slags, old cold slags, and residues to produce zinc oxide fume. The oxide was sent to smelters and refineries for recovery of zinc or it was sold to consumers as zinc oxide. Three plants operated in 1974 as follows: ASARCO at El Paso, Tex., and East Helena, Mont., and the Bunker Hill Co., at Kellogg, Idaho.

Byproduct Sulfuric Acid.—There were eight plants with facilities for roasting zinc sulfide concentrates. Seven plants produced sulfuric acid and one plant operated solely to produce calcine for processing to zinc oxide or slab zinc. In 1974 production of byproduct sulfuric acid from zinc plants was 830,969 tons, up from 819,537 tons produced in 1973.

Zinc Dust.—Production of zinc dust was 50,775 tons in 1974, down 10% from that of 1973. Zinc dust from scrap accounted for 29,075 tons, 57% of the total zinc dust produced.

CONSUMPTION AND USES

Domestic consumption of slab zinc was 1,287,696 tons in 1974, a decrease of 14% from that of 1973. The zinc content of the ore used directly in galvanizing or compounds was 127,113 tons, down from 129,651 tons in 1973. The zinc content of secondary materials to make alloys, zinc dust, and compounds was 258,204 tons, down from 298,336 tons in 1973. Total consumption of zinc for all classes was 1,673,013 tons, a decrease of 13% from that of 1973.

Zinc consumption was reported by 670 users in 1974. Slab zinc for galvanizing accounted for 523,269 tons (41%); zinc base alloys, 440,259 tons (34%); brass products, 181,563 tons (14%); zinc oxide, 65,376 tons (5%); rolled zinc, 39,393 tons (3%); and other, 37,836 tons (3%). Slab zinc used to produce zinc oxide and for other uses showed gains over those of 1973 while the major end use categories showed considerable decreases.

Slab zinc consumption distributed by grade was Special High Grade, 572,851 tons (45%); High Grade, 153,124 tons

---

[24] Work cited in footnote 2.

[25] Chemical Marketing Reporter. Gulf & Western Plans Zinc Units Construction. V. 205, No. 3, July 15, 1974, pp. 3, 21.

[26] Work cited in footnote 14.

[27] Pages 8 and 11 of work cited in footnote 11.

[28] Englehard Minerals & Chemicals Corp. 1974 Annual Report. P. 4.

(12%); Intermediate, 26,345 tons (2%); Brass Special, 122,104 tons (9%); Prime Western, 412,057 tons (32%); and Remelt, 1,215 tons (less than 0.1%). Except for a small increase in Remelt, consumption of all grades of slab zinc decreased from that of 1973. The most significant decline was that in Special High Grade zinc which showed a loss of 166,596 tons. This sharp decrease was attributed to the decline in the diecasting industry primarily due to the slump in automobile production.

Slab zinc consumed at rolling mills was 39,393 tons in 1974, a decrease of 3% from that of 1973. Production of rolled zinc products decreased 7% to 38,417 tons. Strip and foil accounted for 78%, while 17% was used for photoengraving plates. Exports of wrought zinc increased 41% to 3,487 tons but imports more than doubled over those of 1973 to 640 tons. Production of rolled zinc from scrap was 33,474 tons in 1974, yielding a total of 71,891 tons of rolled zinc during the year, compared with 70,202 tons in 1973.

The leading slab zinc consuming States in 1974 were Ohio with 176,819 tons (14%); Illinois, 172,260 tons (13%); Pennsylvania, 166,359 tons (13%); Indiana, 137,178 tons (11%); Michigan, 130,387 tons (10%); and New York, 101,299 tons (8%). These six States accounted for 69% of the slab zinc consumed. Ohio ranked highest in galvanizing and Michigan was the leader in diecasting.

ZINC PIGMENTS AND SALTS

Production.—Published data for zinc pigments and compounds include zinc oxide and zinc sulfate. Information for leaded zinc oxide, lithopone, and zinc chloride was not published in 1971–74 to keep individual company data confidential.

Production of zinc oxide in 1974, 256,355 tons, increased 1.5% over that of 1973. Shipments were 9% lower than production. Zinc sulfate production, 46,135 tons, showed an increase of 5%.

The source of domestic zinc oxide production was 54% from ore and concentrate (American process), 32% from slab zinc (French process), and 14% from secondary material. Zinc sulfate production came from secondary material and from ore or intermediate products. Lead-free oxide was produced by 12 plants in the United States and leaded zinc oxide was produced at only 1 plant. At least eight plants produced zinc sulfate and four produced zinc chloride.

Production of zinc oxide by St. Joe Minerals Corp. was 67,217 tons, reflecting an expansion of production facilities to a capacity of 85,000 tons per year.[30] Two other producers using ores or concentrates as a major source material were ASARCO with plants at Columbus, Ohio, and Hillsboro, Ill., and the New Jersey Zinc Co. Other major zinc oxide producers such as the Eagle-Picher Industries Inc., Hillsboro, Ill., plant and the Sherwin-Williams Co., Coffeyville, Kans., plant, used calcines, fume, and secondary materials as raw materials.

Consumption and Uses.—The apparent consumption of zinc oxide decreased by 10% from about 273,000 tons in 1973 to 246,000 tons in 1974. Analysis of domestic shipments by industry usage showed the rubber industry as consuming 47% of U.S. shipments. Photocopying and chemicals each accounted for 15% of the total. Use of zinc oxide in ceramics, chemicals, and agriculture increased. The rubber industry consumed 16% less in 1974 as the automotive industry experienced declining sales. Agriculture was the chief use for zinc sulfate with lesser amounts going for rayon, flotation reagents, and chemicals. The use of leaded zinc oxide in rubber increased during 1974, but its use in paints declined substantially. Zinc chloride usage, a small part of zinc compound consumption, declined.

Prices.—Zinc oxide and compound prices tended to follow increases in the price of zinc metal. At the beginning of 1974, prices ranged from 22.5 cents per pound for American process zinc oxide to 34.5 cents for French process and to 39.75 cents for electrophotographic grade. On March 14 zinc prices increased 3 cents, after which three companies increased oxide prices by about the same amount. Zinc oxide prices in April steadied at the higher end of the range after the March increase. In July prices again advanced to 37.5 to 41 cents for American process, 39 to 42.5 cents for French process, and 40.5 to 44 cents for electrophotographic grade. Prices climbed slowly for the remainder of the year. At the end of the year most quotations ranged from 40 cents for American process lead-free pigment grade to 41.5 cents for French process and 42 to 44 cents for electrophotographic grade. At yearend leaded zinc oxide, 12%, was quoted at 37.25 cents per pound compared with 30.25 cents in January 1974. The price of zinc sulfate, granular monohydrate industrial, 36% zinc, bags in car load lots, was reported as $24 per 100 pounds in December, up from $18.50 per 100 pounds a year earlier.

---

[30] Work cited in footnote 2.

Foreign Trade.—Exports of zinc oxide increased by 73% during 1974 to a record 12,245 tons, with Canada and Japan receiving about half the total. Lithopone exports increased by 20% to 1,185 tons. Imports of almost all classes of zinc compounds increased in 1974 to a total of 39,436 tons, a 7% gain. As in 1973, zinc oxide, although it declined 6% to 26,088 tons, was the major component of imports of zinc compounds. Mexico, Canada, and France were major sources with other European Community countries contributing small tonnages.

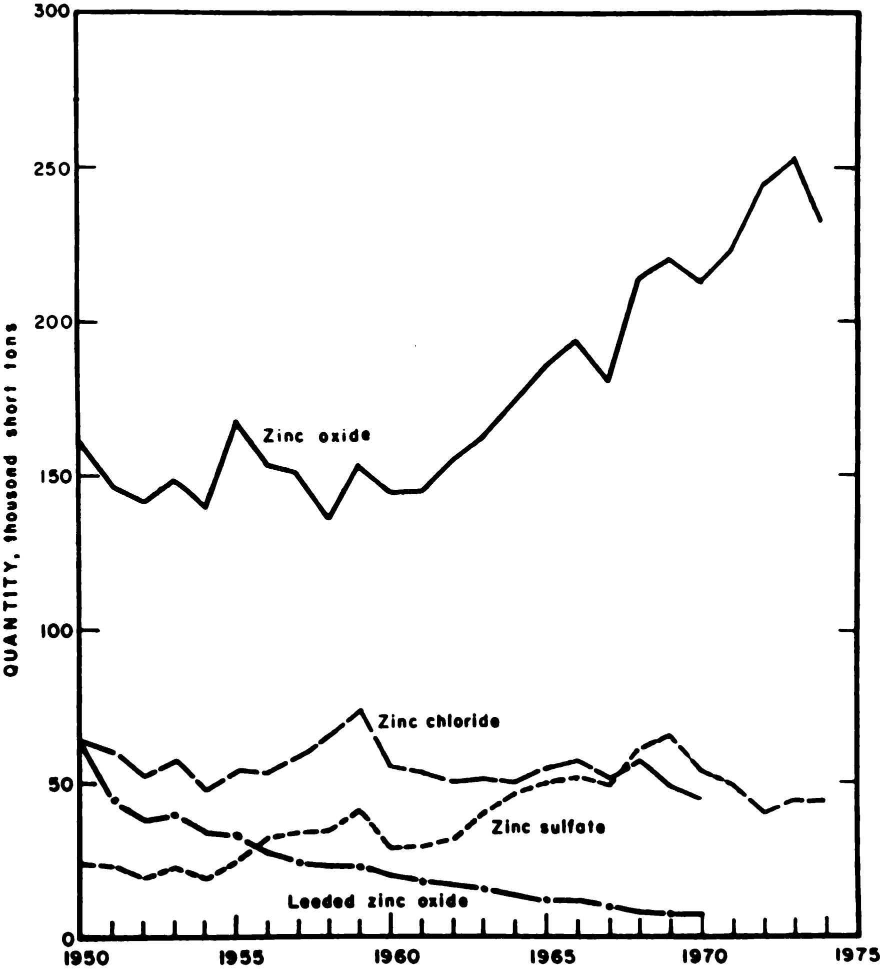

Figure 4.—Trends in shipment of zinc pigments.

STOCKS

Producer Stocks.—Stocks of slab zinc at producer plants at the beginning of the year were 25,947 tons and at yearend were 39,720 tons. The Zinc Institute, Inc., reported that producer stocks were at low levels from May through October.

Consumer Stocks.—Slab zinc inventories at consumer plants were 114,317 tons at the beginning of the year, and by yearend consumer stocks reached a record high of 210,749 tons. Prime Western zinc stocks accounted for the largest increase.

Government Stockpile.—During 1974 the GSA inventory was reduced from 677,009 tons to 391,600 tons.

PRICES

The price for domestic Prime Western zinc ranged from 28 to 32 cents per pound at the beginning of 1974, and the price for Special High Grade zinc ranged from 28.5 to 33.5 cents per pound. Prices increased steadily during the first half of the year. The price for Special High Grade zinc reached 39 to 41.5 cents per pound in July, and that of Prime Western zinc reached 38 to 40 cents per pound in September. These prices remained unchanged through December. Producer prices were quoted f.o.b. smelter or delivered.

The U.S. dealer price for Special High Grade zinc ranged from 75 to 82 cents per pound at the beginning of the year. After a decline, a turnaround took place in late February with steady increases until the price peaked in May at 85 to 87 cents per pound. Prices fell again so that by October the U.S. dealer price was less than the domestic producer price. By yearend U.S. dealer Special High Grade zinc was sold for 34 to 35 cents per pound.

The foreign producers, especially Canada, Peru, and Australia, experienced price increases similar to that of the domestic producers. At the beginning of the year, imported zinc (Prime Western equivalent) was 31 to 36.5 cents per pound. The price increased to a high of 38.3 to 42.5 cents per pound in September. The low side of 38.3 cents per pound remained unchanged but the high side dropped to 39 cents per pound in December.

The European producer price for Good Ordinary Brand (GOB) zinc (Prime Western equivalent) was £300 per metric ton (31.1 cents per pound U.S. equivalent) at the first of the year. The price increased in March to £330 per metric ton and finally to £360 per metric ton (38 cents per pound) in September.

The London Metal Exchange (LME) price for zinc started at £587 to £590 per metric ton (61.3 to 61.7 cents per pound). This price followed the U.S. dealer price with a price drop at the first of the year followed by a gradual increase until May, when it reached £872 to £875 per metric ton (96.3 to 96.6 cents per pound). The trend was reversed once again with a gradual decrease to £300 to £301 per metric ton (31.9 to 32 cents per pound) at yearend.

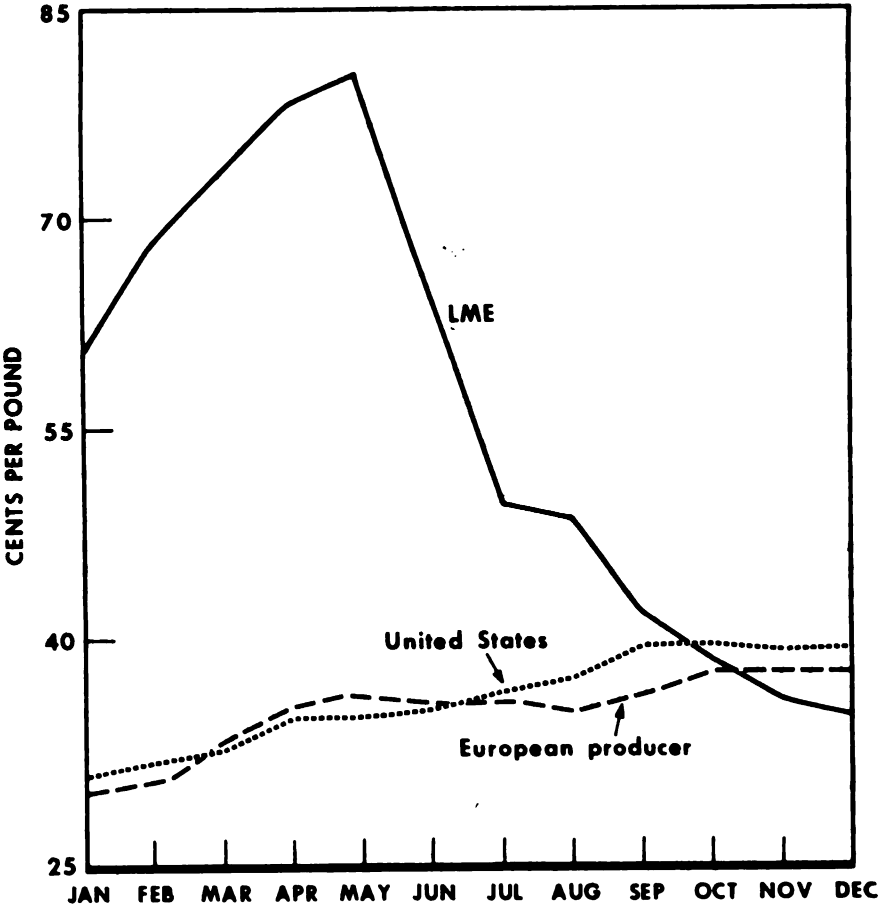

Figure 5.—Average monthly prices in 1974 for U.S. Prime Western zinc and equivalent foreign grade.

FOREIGN TRADE

Exports of unwrought zinc and alloys were 37,927 tons in 1974, a 51% increase over that of 1973. Brazil received 24% of the exports; Belgium-Luxembourg, 12%; the Netherlands, 9%; and Venezuela; 8%. Wrought zinc and zinc alloy exports were 13,078 tons in 1974, of which 39% went to Belgium-Luxembourg and 28% to Canada.

General imports of zinc in ore were 240,043 tons in 1974, an increase of 20% over that of 1973. Canada supplied 68% and Mexico 10%. General imports of zinc metal were 539,538 tons, a decrease of 9% from that of 1973. Canada supplied 270,156 tons, 50% of the total. Other leading suppliers were Japan, Australia, Peru, and Belgium-Luxembourg.

Imports of ore for consumption were 133,733 tons in 1974, a decrease of 13% from that of 1973. The imports for consumption of ore was less than general imports of ore, suggesting a continuing trend of stock buildup of ore at the bonded warehouses. Metal imports for consumption were 543,806 tons in 1974, 1% more than general imports of metal. Metal imports again exceeded the quantity of zinc in imported ores and concentrates. This trend was established 3 years ago with the decline of U.S.-smelter capacity.

There were no changes in the basic tariff rates in 1974. The duty on various zinc materials was as follows: Slab zinc, 0.7 cent per pound; zinc ores, concentrates, and fume, 0.67 cent per pound (based on zinc content less allowable deductions for processing losses); zinc scrap (including skimmings and drosses) 0.75 cent per pound; and zinc dust, 0.3 cent per pound. The duty rate for unwrought alloys of zinc, which includes diecasting alloys was 19% ad valorem.

WORLD REVIEW

Australia.—Mount Isa Mines Ltd. (MIM) postponed startup of its Hilton mine until 1978–79 because delineating of the reserves is expected to take another 4 or 5 years. MIM planned a 50-ton-per-day pilot plant to investigate the McArthur River lead-zinc prospect. The physical properties of the ore have presented metallurgical problems. EZ Industries, Ltd., began mining at Beltana, South Australia. The deposit contains 1 million tons of ore averaging 34.5% zinc and another 237,000 tons averaging 14.8% zinc; the willemite ore required development of new processing methods.

Bolivia.—The New Jersey Zinc Co. announced plans to develop the Huari-Hauri mine northwest of Potosí with an annual output of about 55,000 tons of zinc. The company plans to spend $4 million on the mine and a new flotation mill. The Bolivian Government proposed building an 85,000-ton-per-year zinc smelter at a cost of $50 million. The plant will be strategically located between the northern and southern zinc mining areas.

Canada.—Canada led the world in zinc mine production with 1.28 million tons, a 5.5% decrease from that of 1973. While the Ruttan mine of Sherritt Gordon Mines Ltd., and the Buchans mine of ASARCO registered significantly higher production, seven major mines showed substantial declines in production. The Brunswick Mining & Smelting Corp., Ltd., the Sullivan and H.B. mines of Cominco Ltd., Cyprus Anvil Mining Corp., and Pine Point Mines, Ltd. had decreased output because of labor problems. Lower ore grade led to decreased output by Texasgulf Canada Ltd. (formerly Ecstall Mining, Ltd.) and Mattabi Mines Ltd. Twenty other mines produced at rates about equal to or lower than those of 1973. Ontario was the leading producing province with 36% of the total, followed by Northwest Territories, 15%; New Brunswick, 14%; and Quebec, 11%. Japan, Belgium-Luxembourg, and the United States, all importing about equal amounts, were the leading buyers of Canadian ores and concentrates. Canadian consumption of zinc was about 173,000 tons in 1974, 24% above that of 1973.[30] Canadian smelter production, at 470,000 tons, was 20% less than that of 1973, reflecting losses due to labor strikes and the general shortage of concentrate. Smelter expansions completed or underway in 1974 will raise capacity to 760,000 tons of metal per year.

In Newfoundland, ASARCO produced zinc concentrates from the Buchans mine. The 1,250-ton-per-day mill operated 5 days per week; ore reserves of about 1.5 million tons were expected to last 5 years. Newfoundland Zinc Mines, Ltd., expected to begin production at its Daniel's Harbor mine late in 1975. Annual production of 44,000 tons of zinc in concentrate will come from reserves estimated at 4.5 million tons assaying 8.8% zinc. Noranda Mines Ltd. will purchase about two-thirds of the concentrate.

Imperial Oil Ltd. and Cuvier Mines Ltd. continued exploration work at the Gays River deposit in Nova Scotia. Indications were that ore reserves may be in the 15- to 20-million-ton-range assaying 2% to 3% lead and 5% to 6% zinc.

Because of labor problems, production by Brunswick Mining & Smelting Corp., Ltd., from its mine in Bathurst, New Brunswick, was much lower in 1974. An expansion program at the No. 12 mine is expected to increase capacity to 11,000 tons of ore per day, and the capacity of the No. 12 mill will be increased above its present capacity of 9,800 tons per day. By 1977 the company plans to cease operations at its No. 6 open pit mine, a 3,600-ton-per-day operation. Reserves at the No. 12 mine were about 87 million tons assaying 9.3% zinc and 3.9% lead.[31]

---

[30] Barry, G. S. Zinc: Producers Could Avert Oversupply. Can. Min. J., v. 96, No. 2, February 1975, pp. 81–95.

The expansion program of Heath Steele Mines Ltd. at Little River was about 60% complete. Reserves of 37 million tons contained 4.4% zinc, 1.6% lead, 1.2% copper, and 1.7 ounces of silver per ton. Nigadoo River Mines Ltd., 96.1% controlled by the Sullivan Mining Group, reopened its Beresford mine in February. Mill capacity was being increased to 1,200 tons of ore per day.

Mattagami Lake Mines Ltd., the largest producer in Quebec, installed a new mill and a computerized system for the flotation circuits. Of the zinc concentrate produced, 74% was treated at the Canadian Electrolytic Zinc Ltd. (CEZ) smelter at Valleyfield, 1.5% went to the United States and 24.5% was exported to other countries.[32] Kerr-Addison Mines Ltd. continued to treat ore from the Normetal and Joutel mines, producing 9,661 tons and 5,186 tons of zinc in concentrate, respectively. The Normetal mine continued to operate because of higher metal prices and stable operating costs.[33] Orchan Mines Ltd. treated 364,030 tons of ore including 219,865 tons averaging 6.96% zinc from the main mine and 144,165 tons averaging 1.47% zinc from the new Garon Lake mine. The Norita Division, with reserves of 1.6 million tons grading 7.6% zinc and 0.7% copper, planned to open its mine in 1976.[34]

Other principal zinc producers were Falconbridge Copper Ltd., Manitou-Barvue Mines Ltd., and the Sullivan Mining Group Ltd. In exploration, Selco Mining Corp., and Pickands Mather & Co., uncovered a copper-zinc find in Brouillan township; Noranda bought the Magusi copper-zinc property in Hebecourt township and may be in production by 1979; Patino Mines Ltd. delineated a 625,000-ton ore body assaying 10.8% zinc near Chibougamau; and Abcourt Metals Inc. examined the possibility of mining its zinc-silver deposits in Baurraute township.

Production from the Kidd Creek mine in Timmins, Ontario operated by Texasgulf Canada Ltd. was about 302,000 tons of zinc in concentrate. Metal production was 107,900 tons from the new zinc plant which was operating at its design level of 120,000 tons of metal per year by year-end.[35] The mine and mill complex of Sturgeon Lake Mines Ltd. and Falconbridge Nickel Mines Ltd. was completed. The ore grade averaged 2.1% copper, 7.6% zinc, and 1.1% lead. Ore reserves were estimated to be 2.2 million tons averaging 10.2% zinc, 1.4% lead, 2.8% copper, and 5.8 ounces of silver per ton.[36]

Mattabi Mines Ltd. milled 1.14 million tons of ore grading 8.8% zinc, 0.9% copper, and 0.9% lead. Ore reserves were placed at 11.1 million tons assaying 6.5% zinc. Mattagami Lake Mines Ltd. reported reserves at its soon-to-be-opened Lyon Lake property at 3.1 million tons averaging 6.2% zinc, 1.2% copper, and 0.6% lead.[37] Selco Mining Corp. extended the life of its South Bay mine with the development of a new ore zone.

In Manitoba, the Hudson Bay Mining & Smelting Co. Ltd., reported proven reserves of copper-zinc-ore in the Flin Flon-Snow Lake area at almost 18 million tons assaying 2.7% zinc. Ore production from nine mines was 1.6 million tons. Another mine, the Centennial, was under development. The refinery produced 78,000 tons of Special High Grade zinc. This was the first year that the concentrate feed contained more custom material than company material. Sherritt Gordon Mines Ltd. increased its zinc production through the full-year operation of the Ruttan mine and improved output at the Fox mine. A substantial portion of concentrate production was treated in Manitoba. Production from the two mines was 39,600 tons of zinc in concentrate.[38]

In British Columbia mine production decreased 39% because of a lengthy strike at the Sullivan and H.B. mines of Cominco Ltd. Lower grade ore was mined at the Western Mines Ltd. Buttle Lake mine. The company was considering closing its

Myra Falls mine because of new taxes and low prices. Reeves MacDonald Mines Ltd. produced at a somewhat higher level than in 1973 and reported finding more ore reserves. Other developments included an attempt by Consolidated Columbia River Mines to reopen the Ruth Vermont mine if financing can be arranged; Zaballos Development Company Ltd. outlined 100,000 tons of ore assaying 12.5% zinc; Dolly Varden Mines Ltd. contemplated startup of a 1,000-ton-per-day mine near Alice Arm; and Northair Mines Ltd. scheduled production at its gold-zinc-lead deposit to begin by yearend 1975 at the rate of 300 tons per day.

In the Yukon Territory, Anvil Mining Corp. Ltd. experienced lower production because of labor and transportation problems. The shortage of experienced miners led to lower production by United Keno Hill Mines Ltd. Exploration was very active as Kerr Addison Mines Ltd. and Aex Minerals Corp. discovered a major zinc-lead-silver deposit near Vangorda Creek. There was widespread interest in the Bonnet Plume area where Barrier Reef Resources Ltd. showed 1 million tons grading over 15% zinc, and Placer Development Ltd. continued its activity at Summit Lake.

In the Northwest Territories, Pine Point Mines Ltd. produced at about the 1973 level and began production from the Coronet deposits. Reserves at its Conwest property were about 1.4 million tons grading 9.6% zinc. Nanisivik Mines Ltd., 59.5% owned by Mineral Resources International Ltd., 18.0% by the Canadian Government, and 11.25% each by Metallgesellschaft A.G. of West Germany and Billiton N.V. of the Netherlands, expected to open a lead-zinc mine on Strathcona Sound on Baffin Island. Reserves were estimated at 6.9 million tons containing 14.1% zinc, 1.4% lead, and 1.77 ounces of silver per ton. Production, possibly beginning late in 1976, was expected to be at a rate of 1,500 tons per day.

Denmark.—The Black Angel mine in Greenland, operated by Greenex, A/S, produced 635,000 tons of ore in its first full year of operation. Production of zinc concentrate, which contains small quantities of cadmium and silver, was 185,000 tons. Most of the zinc was sold as concentrate, while the remainder was toll-smelted. Exploration work continued on the development of the Cover ore zone.

Ireland.—Tara Exploration and Development Co. Ltd., deferred development of its Navan lead-zinc ore body as a consequence of the refusal of the Ministry of Industry and Commerce to grant it a mining license that was acceptable to Tara. Tara said it would begin legal proceedings to protect its stockholders and seek damages. According to the company, since 1970 it has invested $38 million at the site, and possibly would have spent another $100 million to bring the mine into full production of about 470,000 tons of concentrate per year. When work was suspended in August, the development shaft had been completed to a depth of 1,122 feet, and over 95,000 tons of ore averaging 11.4% zinc and 2.4% lead had been stockpiled on the surface. Work had commenced on the concentrator and engineering on the process plant was about three-fourths complete. About $5 million was allocated to protection of the local environment.[39]

Mogul of Ireland, Ltd., milled 914,280 tons of ore grading 2.36% lead and 6.58% zinc. Although lower grade ore was treated, concentrate grades improved significantly.[40]

Japan.—Metal production increased 7% as the expanded Iijima smelter of Akita Zinc Co. Ltd. came onstream in September at its full capacity of 170,000 tons per year. Mitsui Mining & Smelting Co. Ltd. struck a rich ore body containing 11% zinc in the Mozumi pit at its Kamioka mine. Proven reserves were estimated at 7.2 million tons with an additional probable reserve of 5 million tons averaging 7.7% zinc. The production rate at the Mozumi pit was 1,600 tons of ore per day.

Mexico.—Industrial Minera Mexico, S.A. (formerly Asarco Mexicana, S.A.) planned to commit a major share of its $160 million investment for integration of its zinc operations. The company slated $96 million for a 121,000-ton-per-year electrolytic zinc refinery to be completed in 1976 at San Luis Potosí. This new capacity would bring Mexico's zinc refining capacity to 330,000 tons per year, or about the equivalent of mine production. Industrial Minera also installed a new mill at its Taxco silver-lead-zinc mine to increase production to 2,400 tons per day. At the San Martín mine in Zacatecas, facilities were being expanded to double production of silver, zinc, and copper by 1976. Two other mines at Pitiquito and Velardeña were scheduled to begin production in 1976.

---

[39] Tara Exploration and Development Company Ltd. 1974 Annual Report. Pp. 5–15.

[40] International Mogul Mines Ltd. 1974 Annual Report. P. 3.

The 115,000-ton-per-year electrolytic zinc smelter at Torreón came onstream. The plant cost $72 million including $12 million for pollution control equipment.

Peru.—Output from the Madrigal mine, operated by Compañía Minera del Madrigal, in which Homestake Mining Co. has an interest, was 14,601 tons of zinc concentrate compared with 11,698 tons in 1973. The copper, lead, and zinc concentrates were sold to Japanese smelters. Compañía Minerales Santander, Inc., a subsidiary of St. Joe Minerals Corp., produced 67,478 tons of zinc concentrate for export, down from 69,725 tons in 1973.

Minero Peru selected a site at Cajamarquilla for a new electrolytic smelter with an annual capacity of 110,000 tons of zinc. The $90 million dollar facility is expected to come onstream in 1978. The plant will treat 175,000 tons of 53% zinc concentrate per year.

Poland.—The Pomorzan mine, reportedly one of the largest lead-zinc mines in Europe, came onstream. The production rate was 650 tons of ore per day with a tripling expected after 2 years of operation. Licensing was granted for the expansion of the Imperial-type smelter at Miasteczko Slaskie. The new unit will replace three horizontal retort smelters in the Katowice area.

Spain.—Cominco Ltd. of Canada planned the development of a lead-zinc mine on the Rubiales property in northwestern Spain at a cost of $43 million. The mine and concentrator were expected to be producing, on an annual basis, 127,000 tons of zinc concentrate and 17,000 tons of lead concentrate from 800,000 tons of ore by mid-1977. Reserves on the property total 7.5 million tons assaying 9.9% zinc and 1.7% lead. The zinc concentrates will be sold to Asturiana de Zinc S.A. for smelting in Spain.

Thailand.—Thai Zinc Co. Ltd., 90% owned by the New Jersey Zinc Co., opened the Mae Sot mine in Tak Province in March. About 80,000 tons of zinc ore was mined in its first 6 months of operation. The company will ship the zinc silicate ore to its pilot plant at Palmerton, Pa., before constructing a 66,000-ton-per-year smelter adjacent to the mine site at a cost of $87 million.

TECHNOLOGY

Bureau of Mines research on zinc was underway at three locations. At the Reno Metallurgy Research Center studies focused on the extraction of zinc as a chloride and its recovery by fused salt electrolysis. A chlorine-oxygen leach was used to recover metal values from complex sulfide concentrates which cannot readily be processed by smelting. In the process most of the sulfide is discarded with the tailings as elemental sulfur. The anhydrous zinc chloride product, after recovery of byproducts, is electrolyzed to yield high purity metal. At the Rolla Metallurgy Research Center a continuous process furnace was tested for recovering slab zinc or powder from zinc oxide contained in flue dusts, and work continued on hydrometallurgical processes for recovering zinc and elemental sulfur from sphalerite concentrates. Researchers at the Salt Lake City Metallurgy Research Center studied cryogenic techniques for the recovery of zinc from the nonferrous fraction of auto scrap.

Results of several research investigations were published by the Bureau of Mines.[41]

The International Lead Zinc Research Organization, Inc. (ILZRO) supported numerous projects in 1974, especially in diecasting, plating, galvanizing, and chemical uses and sponsored several international conferences. Progress reports of these projects are released annually by means of the ILZRO Research Digest.

A comprehensive coverage of zinc-related investigations and an extensive review of current world literature on the uses of zinc and its products are contained in bimonthly issues of the 1974 Zinc Abstracts published by the Zinc Institute, Inc., 292 Madison Avenue, New York, N.Y. 10017, and provided free of charge.

r Revised.

Table 14.—Zinc recovered from scrap processed in the United States, by kind of scrap and form of recovery

(Short tons, zinc content)

Kind of scrap	1973	1974	Form of recovery	1973	1974
New Scrap:			As metal:		
Zinc-base	137,671	122,232	By distillation:		
Copper-base	152,190	136,791	Slab zinc[1]	[r] 83,187	78,535
Aluminum-base	4,035	3,750	Zinc dust	36,202	29,075
Magnesium-base	306	300	By remelting	1,737	1,743
Total	294,202	263,073	Total	[r] 121,126	109,353
Old scrap:			In zinc-base alloys	16,362	15,779
Zinc-base	[r] 46,022	45,722	In brass and bronze	180,674	148,751
Copper-base	38,494	25,733	In aluminum-base alloys	7,961	7,879
Aluminum-base	4,436	3,854	In magnesium-base alloys	546	445
Magnesium-base	106	100	In chemical products:		
			Zinc oxide (lead free)	29,289	32,104
Total	[r] 89,058	75,409	Zinc sulfate	9,444	9,838
Grand total	[r] 383,260	338,482	Zinc chloride	16,639	11,035
			Miscellaneous	1,219	3,298
			Total	262,134	229,129
			Grand total	[r] 383,260	338,482

[r] Revised.

[1] Includes zinc content of redistilled slab made from remelt die-cast slab.

Table 15.—Zinc dust produced in the United States

Year	Quantity (short tons)	Value	
		Total (thousands)	Average per pound
1970	51,136	$20,045	$0.196
1971	50,259	19,691	.196
1972	59,358	24,669	.208
1973	56,154	29,279	.261
1974	50,775	46,398	.457

Table 16.—Consumption of zinc in the United States

(Short tons)

	1970	1971	1972	1973	1974
Slab zinc	1,186,951	1,254,059	1,418,349	1,503,938	1,287,696
Ores (recoverable zinc content)[1]	124,781	119,254	118,305	129,651	127,113
Secondary (recoverable zinc content)[2]	259,864	277,381	307,369	298,336	258,204
Total	1,571,596	1,650,694	1,844,023	1,931,925	1,673,013

[1] Includes ore used directly in galvanizing.

[2] Excludes redistilled slab and remelt zinc.

Table 17.—Slab zinc consumption in the United States, by industry use
(Short tons)

Industry and product	1970	1971	1972	1973	1974
Galvanizing:					
Sheet and strip	253,155	255,335	294,205	321,927	291,008
Wire and wire rope	30,857	29,895	30,769	34,315	27,579
Tubes and pipe	64,479	65,122	64,549	68,048	59,995
Fittings (for tube and pipe)	9,498	10,240	11,106	11,969	9,294
Tanks and containers	3,924	2,759	3,645	2,941	3,203
Structural shapes	18,761	18,589	20,302	21,714	36,784
Fasteners	5,318	5,159	4,310	4,782	5,703
Pole-line hardware	9,938	8,358	8,437	8,193	6,783
Fencing, wire, cloth, and netting	18,114	20,232	21,995	25,418	26,284
Other and unspecified uses	60,205	59,063	58,886	64,530	56,636
Total	474,249	474,752	518,204	563,837	523,269
Brass products:					
Sheet, strip, and plate	61,672	78,929	105,405	109,582	99,971
Rod and wire	41,459	46,514	63,143	63,164	57,725
Tubes	9,086	9,399	8,886	10,858	9,930
Castings and billets	4,606	4,479	6,840	6,000	4,431
Copper-base ingots	9,946	10,440	7,137	6,895	8,244
Other copper-base products	978	725	736	1,151	1,262
Total	127,747	150,486	192,147	197,650	181,563
Zinc-base alloy:					
Diecasting alloy	453,490	504,823	566,932	598,725	436,377
Dies and rod alloy	87	270	56	111	384
Slush and sand-casting alloy	10,059	11,018	12,773	11,770	3,498
Total	463,636	516,111	579,761	610,606	440,259
Rolled zinc	41,065	38,852	45,216	40,763	39,393
Zinc oxide	43,829	40,043	51,992	61,734	65,376
Other uses:					
Light-metal alloys	3,985	4,575	6,300	7,466	9,690
Other[1]	32,440	29,240	24,729	21,882	28,146
Total	36,425	33,815	31,029	29,348	37,836
Grand total	1,186,951	1,254,059	1,418,349	1,503,938	1,287,696

[1] Includes zinc used in making zinc dust, wet batteries, desilverizing lead, bronze powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.

Table 18.—Slab zinc consumption in the United States in 1974, by grade and industry use
(Short tons)

Industry	Special High Grade	High Grade	Inter-mediate	Brass Special	Prime[1] Western	Remelt	Total
Galvanizing	31,794	33,438	9,672	112,874	334,832	659	523,269
Brass and bronze	41,270	101,031	66	7,593	31,516	87	181,563
Zinc-base alloys	433,850	4,757	13	346	986	307	440,259
Rolled zinc	18,997	2,869	16,552	594	381	--	39,393

Total[4]	522,610	181,476	439,952	142,448	1,286,481

W Withheld to avoid disclosing individual company confidential data; included with "Undistributed."

[1] Includes brass mills, brass ingot makers, and brass foundries.

[2] Includes producers of zinc-base alloy for diecastings, stamping dies, and rods.

[3] Includes slab zinc used in rolled zinc products and in zinc oxide.

[4] Excludes remelt zinc.

Table 21.—Production and shipments of zinc pigments and compounds[1] in the United States

Pigment or compound	1973				1974			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Quantity (short tons)	Value[2]			Quantity (short tons)	Value[2]	
			Total (thousands)	Average per ton			Total (thousands)	Average per ton
Zinc oxide[3]	252,475	252,833	$88,378	$350	256,355	232,542	$144,078	$620
Zinc sulfate	43,866	45,197	5,510	122	46,135	44,135	9,048	205

[1] Excludes leaded zinc oxide, lithopone, and zinc chloride; figures withheld to avoid disclosing individual company confidential data.

[2] Value at plant, exclusive of container.

[3] Zinc oxide containing 5% or more lead is classed as leaded zinc oxide.

Table 22.—Zinc content of zinc pigments[1] and compounds produced by domestic manufacturers, by source

(Short tons)

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, North Vietnam also produces zinc, but information is inadequate to make reliable estimates of output levels.

[2] Zinc content of concentrates.

[3] Sum of production by COMIBOL and exports by medium and small mines.

[4] Data are compiled from operating company reports of Tsumeb Corp. Ltd. South-West Africa Co. Ltd. and South African Iron and Steel Industrial Corp., Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine. Data from Tsumeb Corp. Ltd. are for calendar years; data from other companies are for fiscal years ending June 30 of the year stated.

[5] Figure comprises reported production of Tsumeb Corp., Ltd. and South-West Africa Co., Ltd. plus an estimate for Rosh Pinah mine.

[6] Year beginning March 21 of that stated.

[7] Contained in zinc concentrates. Additional quantities of zinc may be contained as a byproduct in lead concentrates produced, but information is inadequate to make reliable estimates of such production, if any.

[1] In addition to the countries listed, North Vietnam also produces zinc, but available information is inadequate to make reliable estimates of output levels.

[2] Includes production from reclaimed scrap.

Zirconium and Hafnium

By Sarkis G. Ampian [1]

Zircon production and sales by domestic mining companies increased 8% in tonnage and 50% in value in 1974 above that in 1973. Zircon exports decreased 26% from 28,921 tons in 1973 to 21,487 tons in 1974 while imports decreased 36% from 98,023 short tons in 1973 to 62,504 short tons in 1974. Exports of zirconium metal and zirconium alloys generally increased in 1974 while zirconium oxide declined. Production of zirconium-bearing compounds for chemicals and refractories also increased. Zircon consumption by foundries decreased from 92,500 short tons in 1973 to 80,000 tons in 1974. Some hafnium was also produced.

The 1974 worldwide zircon supply-demand picture was characterized by an initial strong demand, increasing supply and prices, and a weakening in demand at yearend. Domestically, zircon reflected the worldwide situation and was in tight supply during most of the year because of increased demand, largely in manufacturing specialized refractories and abrasives, which resulted in an inventory problem when shipments abruptly declined in the last quarter. Increased domestic production was more than sufficient to offset the decreased supply brought about by the nearly 40% decline in zircon imports.

Recycling of spent foundry zircon and substitution of chromite and aluminum silicate-minerals for some zircon foundry applications were also commonplace. AMAX Speciality Metals Corp., one of the two zirconium and hafnium sponge producers, and Stauffer Chemical Co., one of the two metallurgical-grade zirconium tetrachloride producers, ceased production in September 1974.

Zircon use was largely in foundry sands, refractories, abrasives, ceramics, and as a source of zirconium metal. The metal was used mostly in nuclear reactors, in corrosion-resistant equipment for industrial plants, and in refractory alloys. Hafnium was used in nuclear reactors, in flashbulbs, and in refractory alloys.

Legislation and Government Programs.—The Statistical Supplement to the Stockpile Report to Congress, December 31, 1974, showed no objectives for zirconium and hafnium materials. Excess stocks of 15,998 tons of Brazilian baddeleyite and 1 ton of zirconium metal powder were sold. The U.S. Atomic Energy Commission (AEC) had an inventory as of June 30, 1974, of approximately one-half ton of zirconium crystal bar and scrap, 937 tons of zirconium sponge, 163 tons of Zircaloy ingot and shapes, one-half ton of hafnium scrap, 5 tons of hafnium oxide, one-half ton of hafnium sponge and shapes, and 39 tons of hafnium crystal bar.

A Food and Drug Administration (FDA) advisory panel submitted a recommendation to FDA challenging the safety of products containing zirconium compounds. The panel suggested that these compounds may break down to form other compounds that could cause lung damage to users. Industry spokesman called the panel's recommendations and suggestions as "hypothetical and speculative" and intimated that conclusive evidence, based on extensive animal inhalation studies on these products, would be presented at an impending meeting and fully exonerate their products from any lung-related problems.[2]

[2] Excludes foundries.

[3] Excludes oxide produced by zirconium metal producers.

DOMESTIC PRODUCTION

E. I. du Pont de Nemours & Co. and Titanium Enterprises, Inc., were the only major producers of zircon mineral concentrate in the United States. Zircon was recovered from mineral sands at the dredging and milling facilities owned by du Pont at Starke, Fla.; by Humphreys Mining Co. for du Pont, near Folkston, Ga.; and by Titanium Enterprises at Green Cove Springs, Fla. Production data were withheld from publication to avoid disclosing individual company confidential data. The combined zircon capacity of these three plants is estimated to be 135,000 tons per year.

Humphreys Mining Co. ceased mining and wet mill operations at Folkston about midyear and resumed these operations at yearend across the St. Marys River at a new deposit near Boulougne, Fla. The company's zircon dry mill was still located at Folkston. Du Pont began constructing a new facility for producing Zircore, their popular new low-cost zircon-aluminum silicate foundry sand.

Ethyl Corp.'s planned operation for recovering heavy minerals, zircon, monazite, rutile, and ilmenite, from the McNairy formation in the vicinity of Kentucky Lake near Paris Landing, Henry County, Tenn. has met with opposition from local environmentalists. The company, by conducting tours through its pilot plant and mine site, was attempting to demonstrate to representative groups that the State's mining regulations will be complied with and that the operation will be both compatible and nonpolluting to the area.

Statistical data on production of zirconium sponge, ingot, and scrap and on hafnium sponge and oxide are also withheld to avoid disclosure of company confidential data. Approximately 2,500 tons of alloys containing from 3% to 70% zirconium was produced in 1974.

Three firms produced 36,400 tons of milled (ground) zircon, a decrease of 26% from the reported 1973 production. Six companies, excluding those that produce metal, produced 11,630 tons of zirconium oxide. Oxide production in 1974 decreased nearly 19% below that reported in 1973.

Hafnium crystal bar, produced by several firms, amounted to 40 tons, compared with 41 tons in 1973.

Table 2.—Producers of zirconium and hafnium materials in 1974

Company	Location	Materials
ZIRCONIUM MATERIALS		
AMAX Specialty Metals Corp	Akron, N.Y	Ingot, sponge.

Do	Parkersburg, W. Va	Oxide.
Babcock & Wilcox Co., Nuclear Materials Div	Leechburg, Pa	Crystal bar.
Teledyne Wah Chang Albany Corp	Albany, Oreg	Oxide, sponge, crystal bars, ingot.

CONSUMPTION AND USES

Zircon consumption in the United States in 1974 was estimated at 167,000 tons. Consumption of zircon concentrate and milled zircon was 80,000 tons for foundries, 40,000 tons of refractories, 15,000 tons for zirconium oxide, 1,600 ton for zirconium alloys (excluding zirconium-base alloys) and 30,400 tons for all other uses. Foundries consumed approximately one-half of the domestic zircon production; the remaining half was consumed by refractory, abrasive, ceramic, metal and other industries. Domestic zircon also was marketed in proprietary mixtures for use as weighting agents, zircon TiO_2 blends for welding rod manufacture, and zircon-refractory heavy mineral (kyanite, sillimanite, and staurolite) sand blends, for foundry sand, and sand-blasting applications. The zircon-bearing foundry sand was reportedly designed to provide consistent high-quality performance at low cost for critical casting applications.

Imported Republic of South Africa baddeleyite ore in 1974 was used principally in the manufacture of alumina-zirconia abrasives and also in ceramic colors, refractories, and for other uses.

Preliminary Bureau of the Census figures for 1974 showed that shipments of zircon and zirconia brick and shapes, composed mostly of these materials, totaled 2.7 million brick, expressed in terms of equivalent 9-inch brick, valued at $11.4 million. In 1973, final figures for shipments were 2.3 million brick valued at $8.3 million.[3]

Zirconium metal was used in nuclear reactors, in chemical plants for corrosion-resistant material, in refractory alloys, and in photography for flashbulbs. AMAX Specialty Metals ceased production of zirconium and hafnium sponge at its Parkersburg, W. Va., plant and zirconium and hafnium mill products at its Akron, N.Y., facility. The first commercial zirconium sponge production was begun at AMAX's New York facility in 1953. Stauffer Chemical Co., supplier of zirconium tetrachloride to zirconium and hafnium sponge producers, AMAX and Teledyne Wah Chang Albany Corp., also ceased production in 1974. Teledyne Wah Chang is currently producing zirconium tetrachloride from zircon at its Albany, Oreg., plant.

Zirconium Technology Corp. (Zirtech), Albany, Oreg., manufacturer of zirconium metal and alloy tubing, announced on December 30 that stockholders approved its merger as an operating division of Kawecki Berylco Industries, Reading, Pa.

Zirconium compounds, natural and manufactured, were used in refractories, glazes, enamels, welding rods, chemicals, and sandblasting. Zirconium chemicals were finding increased application in the paint, textile, and pharmaceutical industries.

Hafnium metal, alloys, and compounds continued to have few uses. The metal was used for nuclear reactor control rods, in special refractory alloys, and in photographic flashcubes. Nonnuclear hafnium metal uses were reportedly increasing.

PRICES

Published prices for regular grade domestic zircon rose from $60 to $250 per ton during the year. Foreign zircon rose from $140 to a high of nearly $600 per ton for certain grades. Prices of zirconium oxides either advanced or were unlisted for the entire year. The prices of zirconium chemicals and zirconium sponge and hafnium metal, sponge, and nitride were unchanged while zirconium powder and sheet prices advanced. The baddeleyite price, furnished by Ronson Metals Corp., also advanced during the year.

Table 6.—Published prices of zirconium and hafnium materials in 1974

Specification of material	Price	
Zircon:		
Domestic, f.o.b. Starke, Fla. (Folkston, Ga.), bags, per short ton [1]		$250.00
Domestic, 75% minimum quantity zircon and aluminum silicates, Starke, Fla. (Folkston, Ga.), bags, per short ton		NA
Imported sand, containing 65% ZrO_2, c.i.f. Atlantic ports, bags, per long ton		560.00
Domestic, granular, 30-ton lots, from works, bags, per ton [2]		440.00
Domestic, milled, 15-ton lots, from works, bags, per ton [2]		500.00
Baddeleyite, imported concentrate: [3]		
98% to 99% ZrO_2, minus 100-mesh, c.i.f. Atlantic ports, ton lots, per pound	0.18–	.20
99+%, minus 325-mesh, c.i.f. Atlantic ports, ton lots, per pound	.56–	.78
Zirconium oxide:		
Powder, commercial-reactor grade, drums, from works, per pound		NA
Chemically pure white ground, barrels or bags, works, per pound [2]		2.22
Electric fused, lump, bags, works, per pound		NA
Milled, bags, 5-ton lots, from works, per pound		NA
Glass-polishing grade, 100-pound bags, 85% to 90% ZrO_2, works, per pound [2]		1.11
Opacifier grade, 100-pound bags, 85% to 90% ZrO_2, per pound [2]		.81
Stabilized oxide, 100-pound bags, 91% ZrO_2, milled, per pound [2]		1.57
Zirconium oxychloride: Crystal, cartons, 5-ton lots from works, per pound [2]		.515
Zirconium acetate solution: [2]		
13% ZrO_2 drums, carload lots, from works, per pound		.22
22% ZrO_2, same basis		.38

FOREIGN TRADE

Exports of zirconium ore and concentrate and zirconium oxide were lower in 1974 than in 1973. Exports of all forms of zirconium metal and alloys, in general, rose in 1974 compared with those of 1973.

Zirconium ore and concentrate, exported to 14 countries in 1974, decreased from 57,842,328 pounds valued at $2,288,128 in 1973 to 42,973,250 pounds valued at $3,323,134. While the quantity exported was 26% below that shipped in 1973 the value rose over 45% to an alltime high. The average value of the zirconium ore and concentrate exported in 1974, $154.66 per ton, represented an increase from the 1973 value of $79.12. This increase was attributed more to the increasing value of zircon than to the larger amounts of higher cost granular and milled zircon shipped. The increase in the amount of higher cost zircon shipped indicated a return to the normal zircon exporting pattern. The major recipients of the exported zirconium ore and concentrate were the Netherlands, 42%; Mexico, 24%; Canada, 22%; Brazil, 4%; and Spain, 3%.

Exports of zirconium oxide totaled 2,055,000 pounds valued at $1,402,167 in 1973 compared with 1,816,497 pounds valued at $1,534,010 in 1974, a decline of 12% in quantity but a 9% increase in value. Zirconium oxide shipments were made to 22 countries. The five major recipients in 1974 were Mexico, 16%; Brazil, Canada, and France, 13% each; and the United Kingdom, 9%.

Total exports of other classes of zirconium increased over 62%, from 1,016,437 pounds in 1973 to 1,650,695 pounds in 1974. The value of this material rose 46% in 1974 to $18,194,996 from the 1973 value of $12,424,733. Of the categories listed, exports of wrought zirconium and zirconium alloys increased 40% in poundage and 48% in value, and those of unwrought and waste and scrap increased 188% in quantity and 73% in value. Zirconium and zirconium alloy foil and leaf exports decreased in both quantity and value in 1974, 13% and 12%, respectively.

Imports for consumption of zirconium ores in 1974 declined to 62,504 short tons, a 36% decrease compared with the 98,023 short tons in 1973. The 1974 figure represents the lowest tonnage of ore imported since 1968 (59,900 tons). Zirconium ore imports from the Republic of South Africa are chiefly baddeleyite (ZrO_2) and prior to 1974 were reported by the Bureau of Census under a separate category giving both quantity and value. Imports of this ore currently are reported under a basket category that reports total value only. It was estimated that approximately 2,950 short tons of South African baddeleyite was imported in 1974.

The average value of imported zircon at foreign ports increased nearly twofold in 1974 to $102.36 per short ton, compared with $51.76 in 1973.

Imports for consumption of zirconium and hafnium in 1974 decreased both in quantity and value in the following categories: Zirconium, wrought; and zirconium alloys, unwrought. Imports for consumption increased in quantity and value in the following categories: Zirconium, unwrought and waste and scrap; zirconium compounds, n.e.c.; hafnium, wrought; and hafnium, unwrought and waste and scrap. In the remaining zirconium oxide category, the quantity imported decreased while its value increased.

WORLD REVIEW

Australia leads the world in production of zircon, which is recovered from sand mining operations along its eastern coast (80%) and in Western Australia (20%). Production of zircon, a coproduct of rutile in east Australia, is expected to remain relatively constant due to lower grades and reserves coupled with persistent environmental problems. Substantial zircon reserves with coproduct ilmenite, on the other hand have been located in Western Australia that, when fully developed, will assure Australia's continuing role in world zircon markets.

Zircon sand is also produced in Brazil, the People's Republic of China, India, Malaysia, the Republic of South Africa, Spain, Sri Lanka, Thailand, and the U.S.S.R.

Baddeleyite is produced in the Republic of South Africa and Brazil and also is found in east Africa, Sri Lanka, and the U.S.S.R.

Australia.—A joint venture was considered between Ionarc/TAFA of Bow, N.H., producers of a plasma-made zirconia directly from zircon, and Associated Minerals Consolidated, Ltd. (AMA) for operating Ionarc's larger plasma furnace facility in eastern Australia.[4] AMA announced intentions to commission a new opacifier plant at Southport, 45 miles south of Brisbane, in early 1975.[5] Installation of new grinding equipment at Brisbane was also planned to treat zircon from its Dunwich operation on North Stradborke Island.

Murphyores Holdings Ltd. and Dillingham Mining Co., a division of Dillingham Construction Pty. Ltd., began site preparation for their jointly owned mineral sand operation on Fraser Island. Construction of a wet mill was planned for the island, over 100 miles off the Queensland coast, north of Brisbane, with the nonmagnetic rutile and zircon fractions to be barged to Maryborough on the mainland for dry milling. The partnership planned to produce 65,000 tons of combined zircon and rutile annually.[6]

[5] Industrial Minerals. No. 78, March 1974, p. 29.

Du Pont (Australia) Ltd. and Allied Minerals NL, partners in Allied Eneabba Pty. Ltd., announced plant construction plans for full-scale mining of mineral sands in the Eneabba area, about 150 miles north of Perth. The decision was based on months of successful pilot plant operations at du Pont's Pigment Department for consumption in their plants. The other minerals, including zircon, rutile, leucoxene, monazite and kyanite, were to be sold on the open market.[7]

Western Mining Corp. Ltd. (WMC) acquired Black Sands Ltd. (BSC), the operation of which will now be carried out under the name of WMC Mineral Sands. The purchase provided WMC an opening into Western Australia's beach sand mining industry. BSC had planned to start developing deposits near Jurien Bay capable of producing up to 3.2 million tons of zircon, rutile, and ilmenite by the first half of 1975. A second deposit at Cooljarloo was reported to be as attractive as that of Jurien Bay.[8]

Consolidated Gold Fields Australia Ltd. (CGF) beach sand interests are held by two producers, Associated Minerals Consolidated (CGF interest 41%) operating on the east coast and Western Titanium N.L. (56%) on the west coast.[9] Western Titanium announced proven reserves of nearly 10 million tons of heavy minerals (double original estimates) at its Eneabba property. An earlier feasibility study detailed mining, engineering, and an analysis of the means of financing the new operation.[10]

Production of heavy mineral concentrates was scheduled by Mid-East Minerals NL, Ltd., in the Busselton Area (Western Australia) in the first part of 1975. Mid-East holds a one-third interest with Westralian Sands Ltd. holding two-thirds. Westralian will both process and sell the output and, to accommodate this new load, was planning extensions of its dry mill and shipping and handling facilities.[11]

Jennings Mining Ltd., a wholly-owned subsidiary of A. V. Jennings Industries (Australia) Ltd., began producing zircon, rutile, and ilmenite concentrates at its wet mill near Eneabba and dry separation plant at Geraldton, north of Perth.[12] Final plans for the Westralian Sands/Lennard Oil NL joint venture at Gingin would complete the picture of the new West Australian beach sands industry.[13]

Brazil.—Prospecting for mineral sands was undertaken by Mineral Deposits Ltd. of Australia and the Brazilian Nuclear Energy Commission. A joint venture between Ishihara Sangyo Kaisha Ltd. and C. Itoh & Co. Ltd. was established to develop unspecified heavy mineral sand deposits.

Canada.—Noranda Metals Corp. reaffirmed its intentions to construct a tube mill at Armprior to supply both nickel- and zirconium-base alloy tubing to the nuclear power industry.

Egpyt.—The main resource of zircon and other heavy minerals, chiefly ilmenite, magnetite, rutile, monazite, and garnet, were the black sands occurring at different localities along the Mediterranean coast. Reserves of these heavy minerals, over an explored area, were estimated at more than 4 million tons.[14]

Gambia.—A cooperative agreement was signed with the Government of Iceland to jointly establish a heavy minerals separation plant in Gambia and an ilmenite electrosmelting plant in Iceland. These plans were reportedly contingent on the outcome of feasibility studies underway and did not stipulate the disposition of the nonmagnetic rutile and zircon fractions.[15]

Guinea.—Renegotiations of concessions granted earlier were underway to expedite exploitation of Guinea's zircon- and ilmenite-rich beach sands.

India.—Indian Rare Earths Ltd. planned to establish a $45 million facility at Gopalpur in Orissa to recover and process the State's beach sand deposits. This Government-owned company completed an expansion at its Manavalakurichi plant in Tamil Nadu to 30,000 tons per year. Increases in zircon output were not specified.[16]

Table 12.—Zirconium concentrate: Non-Communist world production, by country

e Estimate. p Preliminary. r Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Revised to zero.

[2] Exports (production not officially reported; exports believed to closely approximate total output).

[3] Production not officially reported; data presented are total recorded imports of zirconium ores and concentrates from the Republic of South Africa by the United States, Japan, and West Germany. As such, listed figure may be only a part of total output.

[4] Officially reported production.

Liberia.—A Dutch syndicate comprised of Wm. H. Muller N.V., Bos Kalis-Westminister Dredging Group and Hoogovens, and the Liberian Beach Sands Exploitation Co. continued its detailed exploration program in the southeastern part of the country for zircon, rutile, monazite, and ilmenite reserves. Bulk beach sand samples from selected areas have been shipped to Australia for combined mineral dressing and pilot plant tests.

Norway.—Plans for a $12 million "Norzon" (a zirconia-alumina abrasive manufactured from zircon, zirconia, and alumina mixtures) plant was announced by the Norton Co. The plant, scheduled for completion in 1976, is to be located at Evje on a 15-acre site.[17]

Sierra Leone.—Sierra Rutile Ltd., a group consisting of Bethlehem Steel International Corp. (85%) and Nord Resources Corp. (15%), successfully completed pilot plant tests on wet milling, geological work, and optimization of the mining method. The company concluded that commercial mining and milling could only proceed with suction dredging. Tests using dry mining methods, bucket wheel excavators, and dragline-dredge systems, were not promising. Detailed planning for production was underway.[18]

The Bayer-Preussag Mining Co., a joint venture of Bayer Aktiengesellschaft A. and Preussag A., both of West Germany, completed the first phase of exploration for heavy minerals in the Moyamba District of the Southern Province. Ore deposits containing fair amounts of rutile and heavy minerals were mapped, evaluated and sampled, and the firm was awaiting results from preliminary extractability tests prior to pilot plant investigations.

The Government's Geological Survey Div. was systematically examining other areas of black beach sands along the southern coast for ilmenite, monazite, and zircon.

South Africa, Republic of.—At Richards Bay, Quebec Iron & Titanium Corp. of Sorel, Canada (QIT), undertook feasibility studies with the Industrial Development Corp. of South Africa and Union Corp. QIT obtained a 50% interest in the project during the year and a decision is expected in 1975 if the scheduled annual production of zircon (125,000 tons per year), as well as rutile and titanium slag, will start in 1977 under the auspices of the new company—Tisand Pty. Ltd.

[17] Industrial Minerals. No. 81, June 1974, p. 64.

[18] Mining Journal (London). Mining Annual Review, 1975. West Africa–Sierra Leone. June 1975, pp. 436–437.

Baddeleyite concentrates are produced at Phalaborwa, South Africa, by Phosphate Development Corp. Ltd. (FOSKOR) and by Palabora Mining Co. Ltd. (PMC) mining contiguous deposits in the Palabora igneous complex. These baddeleyite concentrates, pure (97% ZrO_2) and ultrapure (99+%), are coproducts from copper, phosphate, and iron operations, and were favorably received by the abrasive, ceramics, and refractory industries. Plant expansions are presently underway at both locations. The radioactivity associated with these baddeleyite concentrates, contaminating uranium and thorium mineralization, was readily removed by further combined pulverizing and acid treatment, resulting in the ultrapure 99+% grade.

Sri Lanka.—Expansion was still underway at the State Mineral Sands Corp. Pulmoddi heavy minerals operation 30 miles north of Trincomalee on the Bay of Bengal. Zircon production of 8,000 tons per year was targeted for 1976. Presently only very small quantities are produced.[19]

Tanzania.—A Government company, Beach Sands Mining Ltd. has been formed with Romanian partners to develop beach sand deposits on Tanzania's Indian Ocean coast. Heavy mineral production has already started on a pilot plant scale.[20]

Thailand.—Plans were announced by the S. A. Sands (Phuket) Co. to establish a beach sand mining operation at Prachuap Kiri Khan to produce 5,000 tons of zircon and 1,500 tons of rutile annually.[21]

United Kingdom.—Imperial Chemical Industries Mond Div. commenced production of its stabilized zirconia fibers, "Saffil," at Widnes in Lancashire.

TECHNOLOGY

The Office of Coal Research (OCR), U.S. Department of the Interior, announced granting of two major contracts under the July 1973 U.S.-U.S.S.R. Memorandum of Understanding involving joint research in magnetohydrodynamic (MHD)[22] electric generation[23] and cosponsorship of an international MHD conference.[24] In further MHD research, the OCR awarded contracts to university, industry, and government laboratories.[25]

The two major contracts were to provide the preliminary design of a channel to test the generation of electricity from coal by the MHD process in a Soviet pilot plant. The MHD conference scheduled for June 9–13, 1975 in Washington, D.C., is expected to draw MHD specialists and power engineers from all over the world, with the two largest contingents to come from the United States and the U.S.S.R. The conference is to emphasize three main topics: Open-cycle MHD systems; plasma closed-cycle MHD systems; and liquid metal closed-cycle MHD systems. All papers delivered at the conference are scheduled for publication in preprint volumes for distribution at the meeting.

Other MHD contracts of interest awarded by the OCR were research projects undertaken by the Massachusetts Institute of Technology (MIT), the University of Tennessee Space Institutes (UTSI), and the National Bureau of Standards (NBS). The MIT effort was to both provide technical advice to OCR on their MHD program and to coordinate an effective materials program. Candidate zirconia-based electrode and insulator materials and their relative advantages and disadvantages under various duct environments were identified. Protocols for testing these electrodes and insulator materials under seed and slag attack in bench scale and experimental duct scale were outlined, and a cooperative test program for these zirconia materials in the UTSI MHD duct under coalfiring conditions was organized.

[21] Mining Journal (London). Mining Annual Review, 1975. Far East–Thailand. June 1975, pp. 395–396.

[22] MHD involves generating electricity without the rotating parts associated with the less efficient conventional steam turbine generating systems. Coal-fired MHD systems are fired at high temperatures and pressures, and the resulting gases are forced through a duct at high velocities. The gases move through a magnetic field surrounding the duct, resulting in the generation of an electric current. The ultrahigh-temperature MHD systems are more efficient than lower temperature MHD systems and use stabilized zirconia electrodes and insulator materials in the ducts.

The Energy Conversion Division of the UTSI, was working on the direct MHD conversion of coal to energy. This MHD generator was the only one in the world producing electric power using coal as a fuel. The program at NBS concerned high-temperature materials and consisted of coal slag characterization, vaporization studies, and electrical conductivity measurements of zirconia-based MHD electrode and insulator materials. The interactions of the various reaction products and noncombustibles resulting from coal combustion were also stressed in this work.

Bureau of Mines research efforts were directed toward lowering the cost of producing nuclear-grade zirconium and hafnium material, developing advanced refractory molybdenum-zirconium-hafnium alloys, and zircon desilication.[26] Research on reducing the production costs of nuclear-grade material centered on substituting an aliphatic amine technique for the conventional, more expensive and flammable methyl isobutyl ketone method of purifying zirconium by removing hafnium down to levels of 100 parts per million or less. This work has also shown that these amines were more completely recoverable than the ketone, which was inhibited by its slight water solubility. The advanced molybdenum-zirconium alloy research consists of three integrated phases: (1) Castability of alloys, (2) stable oxide coatings, and (3) casting oxidation resistance metal protective coatings. The compositions included in this research were TZM (Mo-0.5Ti-0.08Zr-0.015C) and binary molybdenum alloys containing various levels of zirconium and hafnium. Research on the stable oxide coatings was of particular interest. Spinel and perovskite structures were judged to be suitable candidates for oxidation-barrier coatings for these refractory alloys. In the highly important thermal expansion match between the coating and the alloy, studied experimentally with cross sections, spinels were closer than perovskites, and the chrome spinel variety, more closely matched than the aluminum type. This thermal expansion match with a chromium-bearing compound should greatly reduce bonding problems generally associated with mating oxides and alloys.

The Bureau also investigated possible methods for selectively removing the SiO_2 component of silicate minerals and ores. Methods were described for removing SiO_2 from selected zircon and aluminum ores as volatile silicon sulfides by treating with sulfur and carbon; with sulfur, carbon, and a reducing gas; or with sulfur compounds and carbon. Preliminary results should complete desilication of zircon at 1,450° C.

The geology, with particular emphasis on stratigraphy, heavy mineral suites, and ore body trends, of the Green Cove Springs and Boulougne heavy mineral sand deposits of Florida was published.[27] This work was done in close cooperation with the three domestic zircon producers: Titanium Enterprises, Inc., Humphreys Mining Co., and E. I. du Pont de Nemours & Co. A publication on the geology and mineral potential of South Vietnam indicated that much of the coastal areas contain zircon and other heavy mineral sands.[28] The area immediately north of Cam Rahn Bay in Thau-Thein Province appeared to be the most promising for zircon, monazite, and titaniferous mineral exploitation. The description and interpretation of an unusual occurrence of baddeleyite in the maficigneous rocks of the Canadian Arctic Archipelago were given.[29]

The presence of garnet-zircon-rutile, monazite, and ilmenite totaling nearly 50% of the heavy mineral fraction were found in the thin but persistent garnetiferous Northumbrian beach sands on the North Sea.[30] A reexamination of the extensive inland dune sands, on the other hand, appeared to merit further investigation of their heavy mineral potential. The use of large throughput dredges were advocated because of the less than 1% heavy minerals. The world zircon producers, led by Australia and the United States, their operations, and expansion plans were highlighted.[31]

[30] Gallagher, M. J. Rutile and Zircon in Northumbrian Beach Sands. Trans. Inst. Min. Met. (Sec. B: Appl. Earth Sci.), v. 83, No. 813, August 1974, pp. B97–B98.

Shifts in the world's mineral supplies over the years were documented with selected minerals, such as Australian zircon.[32] Predictions of smaller demand, higher prices, and less waste were advanced. The availability of zircon supplies during the year, coupled with the ample supplies of chromite, their mutual substitutability in foundry applications, and their price comparability were explored.[33]

A novel hot Clerici-solution laboratory procedure for separating constituents of the nonmagnetic heavy mineral fraction, zircon, monazite, rutile, and spinel was described in a work analyzing the economic potential of Liberian beach sands.[34] The pumping of heavy minerals to the surface after concentration in a submerged hydrocyclone was studied with both a laboratory "micro-hydrocyclone" and a commercial unit.[35] This technique if commercially feasible would revolutionize the heavy mineral sands industry.

Richert cones, high-capacity rougher devices treating feeds between 2 millimeters and 350 mesh, have been known to have a limiting capacity above which the recovery drops off sharply. It was believed that this shortcoming, attributed to the inability of the slots to take a constant proportion of the solids at higher feed rates, has been overcome by a new slot profile. The cone's conventional sharp-edged adjustable slots were simply replaced with a new curved surface. Tests indicated that this new curved surface slot not only improved separation efficiency over a wide range of conditions but also wore better and did not block as readily.[36]

Work on plasma methods for producing zirconia from zircon,[37] zirconia or zirconium salts from zircon,[38] and zirconium and hafnium values also from zircon,[39] were described in patents. The plasma method for producing zirconia employs heating a finely divided zircon concentrate above its dissociation temperature, avoiding particle coalescence, to form extremely small zirconia crystallites and glassy amorphous silica. The hot dissociated zircon is quenched rapidly, and glassy silica is leached out with a sodium hydroxide solution leaving the insoluble zirconia crystallites. The production of either zirconia or a zirconium salt involves heating a stoichiometric mixture of limestone and zircon at a selected time and temperature to form calcium zirconate and tricalcium silicate clinker. The clinker is carefully cooled to first convert the tricalcium silicate to dicalcium silicate and lime. Further cooling results in the disintegration of the clinker into a very fine powder composed of dicalcium silicate and lime and coarser calcium zirconate crystals that are readily classified. The acid-soluble calcium zirconate crystals are treated with either acids or other reagents forming oxides or salts. The last patent outlines an elaborate procedure involving water slurrying the zircon with zinc oxide and phosphoric acid, treating with calcium carbonate, boiling with a sodium carbonate solution, all interspersed with decantation and washing steps. The separated solids are finally smelted to the base metal.

The investment casting industry, a large zircon sand and flour consumer, and its capability of delivering casting competitively with other metal forming techniques was detailed.[40] A table was also included depicting the industry's flexibility by listing cobalt and nickel base alloys, carbon and low steels (iron base), and selected miscellaneous ferrous alloys that are amenable to investment casting.

The manufacture of a novel unfired zircon-pyrophyllite refractory brick containing selected grain sizes of these two minerals bound with sodium silicate was patented.[41] This refractory brick should find wide application in modern steelmaking if it remains competitively priced. The refractory has excellent corrosion resistance at elevated temperatures to both molten steel and slags.

A brief manual on ceramic and refractory coatings and their applications in preventing either wear or corrosion was prepared.[42] The superior wear, refractory, and thermal insulation properties of the zirconium and hafnium borides, carbides, and oxides were noted. The manual only considered the four principal flame spray methods: (1) Oxyacteylene, (2) oxyhydrogen, (3) detonation, and (4) plasma.

A new family of lightweight, inorganic "Saffil" fibers, a yttria-stabilized zirconia and an alumina, was comprised chiefly of zirconia and alumina crystallites in the range from 50 to 500 angstroms.[43] These small crystallites lend strength to the fibers and when stabilized in a glassy and/or amorphous matrix, tend to inhibit both disruptive crystal phase transitions and crystallite growth at elevated temperatures. The zirconia fibers remain intact up to 1,600° C and resist attack by most acids and alkalies. Saffil will probably be used in thermal insulation, refractory surface repair, and filtration. The unusual characteristics of zirconia and yttria-thoria ceramics were being used as solid electrolytes in new approaches to oxygen measurement, hydrogen production, electric power generation, and air and water pollution control.[44] The unusual characteristics of these materials, dielectrical insulators at low temperatures but electrically conducting at elevated temperatures, can be further modified by controlling the type and amount of the stabilizers (calcia, yttria, or magnesia) used in their formulation.

The basic concepts for thermochemical hydrogen generation processes, including economic comparisons and uses, have been summarized.[45] A solid-membrane, open-cycle hydrogen generator, with a solid zirconia-bearing electrolyte, was reported to offer better potential for cheaper production of hydrogen than conventional electrolysis. The most important single barrier to new large-scale uses of hydrogen, for energy and chemical feedstocks, has been the high cost of hydrogen compared with other clean energy sources.

A comprehensive article dealt with the industrial importance of zirconium compounds.[46] The article discussed the fundamental properties and aqueous chemistry, the bonding between hydrous zirconium dioxide (HZD) and other substances, and the source of HZD. The hydrolysis and its implications along with the molecular structure of HZD were detailed in the aqueous chemistry section. The sources of HZD, zirconyl acetate and formate, ammonium and alkali metal zirconyl carbonates and the fluorozirconates, were afforded a similar detailed treatment. The superior bonding properties of HZD have found widespread application in the textile, paper, paint, polish, and cosmetic industries. The newer successful commercial applications for HZD compounds have been paper coating, polishes, emulsion paints, antiperspirants, and several textile finishing processes. The versatility of the HZD compounds is readily demonstrated by two applications. In paper coating and in polish formulations, a water-soluble zirconium compound is used to impart resistance to water and to improve film strengths. In the second application, for emulsion paints, zirconium compounds have been developed to impart reversible gel properties in nondrip paint.

A method of metal labeled stable isotope dilution (MLSID) has been developed that permits the ready determination of zirconium in geological samples.[47] Previous methods were both difficult and subject to large variations in reported zirconium concentrations.

Hydrozirconation was reported to be more desirable than many synthesis procedures employing hydroboration or hydroalumination.[48] The alkyl zirconium complexes used in hydrozirconation are less expensive, easier to prepare, and have higher organic product yields than their air-sensitive boron and aluminum analogs.

A novel isostatic hot pressing system, without molds, was successful in eliminating residual porosity normally associated with sintered lanthanum-modified lead zirconate-lead titanate (PLZT) polycrystalline ceramics.[49] This pressing method, with the pressure transmitted with inert gases, requires lower pressures (50 to 200 bars) and temperatures (usually 1,000° C lower) than conventional PLZT sintering temperatures. Pore-free ceramics, which have been densified to virtually theoretical density, with their number continually increasing, find use in transparent PLZT ceramics for electrooptics, as well as piezoelectrical ceramics based on PZT for surface wave filters. Fabrication of translucent PLZT ceramics by conventional hot pressing[50] and a technique for determining the temperature sensitivity on the electrooptic effects and dielectric constants have been outlined[51] in articles. In related PLZT work, a new ceramic window has been developed for airplanes, which, when electrically activated, switches from transparent to opaque.[52]

The fracture toughness of partially stabilized ZrO_2 (PSZ) was related to a simple correction factor.[53] PZS ceramics and refractories are superior in thermal shock properties to conventional fully stabilized zirconia. Thermal shock structures of PSZ in the binary system CaO-ZrO_2 were studied.[54] The brittleness of a thermally shocked specially prepared batch, due to extensive microcracking, was thought to arise from both the large volume of the monoclinic ZrO_2 present and from the hardness of the host cubic ZrO_2 matrix. In another work on PSZ, the role of SiO_2 in commercial ZrO_2 products were investigated.[55] Silica enhanced the sintering of zirconia partially stabilized with either CaO or MgO but contributed to increased fired shrinkage. The possible mechanisms of sintering enhancement and the concentration of the stabilizer and the SiO_2 impurity at the grain boundaries were also discussed.

Heating dehydrated amorphous ZrO_2 and subsequent study by X-ray and electron diffraction, and Raman scattering revealed the presence of an induced metastable tetragonal ZrO_2 followed by conversion to the stable monoclinic ZrO_2 phase.[56] This definitive study with Raman scattering measurements, a technique sensitive to intermediate-range order, has succeeded in explaining the crystallization sequence of amorphous zirconia mixtures obtained during commercial drying steps. In a related work, the crystallization sequence was further refined and attributed to 2 weight-percent OH- ions, which were concentrated on the ZrO_2 surfaces, domain boundaries, and occasionally in the lattice.[57]

The directional solidification (DS) of the ZrO_2-MgO eutectic has been studied thoroughly.[58] The eutectic composition was located at 27 weight-percent MgO with DS of this composition yielding MgO rods in a cubic ZrO_2 matrix. Annealed compositions, 24 hours at 1,200° C, increased in fracture strength by 50% over their unannealed room-temperature counterparts. The control of microstructure and design of ceramic materials has been the subject of considerable research, with the objective of maximizing a particular mechanical, optical, electrical, magnetic, or other property. DS has been investigated extensively in metallurgical systems. The formation of $CaZrO_3$, a major sinter product in the limestone-zircon process for ZrO_2 production, in the solid state has been researched.[59] The compatibility relations in the system SiO_2-ZrO_2-P_2O_5, which includes the ore mineral zircon, and zirconium chemicals used in ceramic and refractory manufacturing, was established by quenching, annealing, X-ray diffractometry, and optical microscopy.[60]

The AMAX Zr-Hf Newsletter, devoted to abstracting zirconium and hafnium technology, ceased publication with its August 1974 issue.[61] Many of the articles were devoted to the production and use of zirconium and hafnium as compounds, as metal alone, in alloys and as alloying elements, not only in nuclear applications but also in refractory and oxidation- and corrosion-resistance technology.

A carbothermic reduction method for the production of zirconium metal from its oxides was patented.[62] The method involves reacting the oxide with carbon in a molten metal solvent, preferably tin, copper, or iron, forming carbon monoxide and free metal in solution with the solvent. In an embodiment, the reduction in a nitrogen atmosphere forms a metal nitride that can be further processed by the molten metal solvents. The pure metals in solution can be recovered by conventional phase separation methods. This new process was expected to lower the price of commercial- and nuclear-grade zirconium metals and alloys.[63]

A new alloy, known as zirconia grain stabilized (ZGS) platinum was reported to be stronger and more creep resistant than the conventional high-temperature rhodium-platinum alloys.[64] ZGS platinum was expected to replace conventional platinum alloys where high-temperature strength is required. Optical glass stirrers and glass holding bowls were two uses cited. Another new alloy, applicable in gas turbine engines, using directionally solidified eutectic techniques was announced.[65] This nickel-base wrought-type alloy contains hafnium and zirconium.

The improved corrosion resistance of metal systems containing small amounts of added zirconium were investigated by Auger electron spectroscopy.[66] The breakdown by oxidation of the protective zirconium carbide or nitride skin, formed during metalworking, was observed starting as low as 500° C with the zirconium degassing as an oxide above 1,500° C. The use of standard free energy data and phase equilibria predicted the compounds formed on adding the rare-earth elements and zirconium metal to steel.[67] The rare-earth and zirconium oxides, strong steel deoxidants, were desirable because their high melting points allowed sufficient retention time to be effective. The use of zirconium and selected desulfurizers in improving the formability of high-strength, low alloy (HSLA) steels was discussed. HSLA steels are used in drilling rigs and in pipelines.

The hardness of the refractory ZrB_2 and HfB_2 was studied at elevated temperatures.[68] These hard and brittle room-temperature compounds decreased in hardness with increasing temperature. The studies conducted with a high-temperature microscope specially equipped with a microhardness tester were correlated with the unit cell dimensions of the diborides determined by X-ray diffractometry. The authors suggested that the microhardness and X-ray techniques were more reliable since the information affecting the microstructure, such as grain size and porosity were rarely provided.

ARSENIC [1]

Legislation and Government Programs.—As a result of studies indicating a possible correlation between arsenic exposure and cancer frequencies, meetings were held in September to consider new standards of allowable arsenic concentration in the air. The Occupational Safety and Health Administration (OSHA) scheduled an informal public hearing for early 1975 on recommendations for exposure standards for inorganic arsenic.

Domestic Production.—Arsenic trioxide (As_2O_3) was produced domestically only at the Tacoma, Wash., copper smelter of American Smelting and Refining Company (ASARCO Incorporated). Production data cannot be published. Output was adversely affected by a month-long strike and was 27% below that in 1973. Shipments were the largest since 1945 and were more than double production. As a result, stocks at yearend were 78% less than those at the beginning of 1974 and the lowest since 1968.

Consumption and Uses.—Apparent consumption of arsenic, essentially all as white arsenic (As_2O_3), increased 15% over that in 1973. Calcium and lead arsenate were the principal end products. Minor quantities of arsenic were used in sodium arsenate and other chemical compounds.

Production data on calcium arsenate may not be published but usage, as measured by disappearance at the domestic producers level, was 650 tons in 1973 compared with 876 tons in 1972. Lead arsenate production totaled 1,973 tons in 1973, 24% less than that in 1972. Disappearance for all domestic uses was 1,503 tons, down 40% from that in 1972.

Arsenical compounds used in wood preservatives continued as an important use of arsenic. Consumption of chromated copper arsenate (CCA compounds) increased for the sixth consecutive year; 5,834 tons, 20% more than that in 1972, was consumed in 1973. The use of fluor chrome arsenate phenol (Wolman salts and osmosalts), on the other hand, has trended downward since 1969. Consumption of 842 tons in 1973 was 12% less than that in 1972.

Small quantities of high-purity arsenic were used in the manufacture of gallium and indium arsenides for semiconductors.

Prices.—The price of refined white arsenic, 99.5%, at New York docks, was quoted at 6 to 6¾ cents per pound at the beginning of 1974. On January 24, the price was 6½ cents per pound which held through yearend. Refined white arsenic at Laredo was $165 per ton in early 1974, rose to $210 per ton on June 3, and remained at this level throughout the remainder of 1974.

Arsenic metal was quoted in London at

---

[1] Prepared by Gertrude N. Greenspoon, mineral specialist.

£800 to £1,000 per metric ton (87.1 to 108.9 cents per pound) until February 19 when it rose to £1,500 to £2,000 per metric ton (163.3 to 217.7 cents per pound) where it remained throughout yearend.

Foreign Trade.—No exports of arsenic metal or white arsenic were reported.

Imports of white arsenic rose 2% over those of 1973. Sweden, the principal supplier, furnished 50% and Mexico supplied 45% of the total receipts. Of the 25 pounds of arsenic sulfide imported, all came from the United Kingdom; 84,700 pounds of arsenic compounds were received in 1974, most of which came from the United Kingdom, and most of the 266,000 pounds of sodium arsenate also came from the United Kingdom.

Receipts of arsenic metal were 707 tons, 10% more than in 1973. Sweden supplied 605 tons, the People's Republic of China 50 tons, Canada 31 tons, and West Germany 21 tons. Less than 1 ton each was received from Japan, the Netherlands, Switzerland, Belgium-Luxembourg, and the United Kingdom.

Tariff.—Arsenic oxide (white arsenic) enters the United States duty free. A 1.2-cent-per-pound duty was applicable to arsenic metal.

Table 1.—U.S. imports for consumption of white arsenic (As_2O_3 content), by country

[1] Less than ½ unit.

World Review.—World production of white arsenic rose 7% in 1974. A nearly twofold increase in output in Mexico more than offset a 19% decrease in South-West Africa. Production in other countries was little changed from previous years.

Technology.—Research conducted by ASARCO indicated that arsenic metal can be used to improve cast iron strength[2] and this development apparently was a factor in the decision for the startup of a new facility at Tacoma to produce metallic arsenic. Also, at Tacoma construction was underway on a new system for handling arsenic-bearing dust.

[1] Including calculated arsenic trioxide equivalent of output of elemental arsenic and arsenic compounds other than white arsenic, where inclusion of such materials would not duplicate reported white arsenic production.

[2] In addition to the countries listed, Austria, Belgium, the People's Republic of China, Czechoslovakia, East Germany, Finland, Hungary, Southern Rhodesia, the United Kingdom, and Yugoslavia have produced arsenic and/or arsenic compounds in previous years but information is inadequate to ascertain whether such production has continued or not, and if so, at what levels.

[3] Output of Tsumeb Corp. Ltd. only.

A report summarizing the abundance and distribution of arsenic in soils and other surface materials throughout the United States indicated that the average for the entire U.S. was 5.8 parts per million. The average for the Western States was 6.1 parts per million and for the Eastern States 5.4 parts per million. Clusters of high values appeared in the central part of the Cordilleran Mountain region, the Ozark region, and parts of the Appalachian Highland region that may reflect the arsenic content of the parent geologic materials.[3]

CESIUM AND RUBIDIUM[4]

Domestic Production.—There was no domestic production of cesium- and rubidium-bearing minerals during 1974. The likelihood of any future domestic production of such minerals remained poor. Imported pollucite was the source of domestically produced cesium and its compounds. A residue from the processing of lithium ores in previous years known as *ALKARB* provided the source of domestically produced rubidium and its compounds.

Total production of cesium chemical compounds increased significantly in 1974, and production of rubidium chemical compounds declined by more than one-half of that of 1973.

The following companies produced cesium and rubidium chemicals during the year: Kawecki Berlyco Industries, Inc., Revere, Pa.; Kerr-McGee Corp., Trona, Calif.; and Great Western Inorganics, Inc. (formerly Rocky Mountain Research, Inc.), Golden, Colo. No production of cesium and rubidium metal was reported, but small quantities of both metals were shipped from existing stocks.

Consumption and Uses.—Data, relating to the consumption and end use pattern of cesium and rubidium metals and compounds, were not available. These materials found commercial application in the manufacture of pharmaceuticals, ultracentrifuge separation of organic compounds, and electronic apparatus such as scintillation counters, photomultiplier tubes and photoelectric cells. Cesium, rubidium, and their compounds can be substituted for each other in some end uses.

The Office of Coal Research, U.S. Department of the Interior, continued to fund magnetohydrodynamic (MHD) electric generation research. If MHD electrical generation is successfully developed in this decade demand for cesium may be generated to enhance MHD plasma.

Prices.—During the year the American Metal Market quoted a nominal price for pollucite containing about 20% cesium

[3] Shacklette, H.T., J.G. Boerngen, and J.R. Keith. Selenium, Fluorine, and Arsenic in Surficial Materials of the Conterminous United States. U.S. Geol. Survey Circ. 692, 1974, pp. 10-11.

[4] Prepared by Benjamin Petkof, physical scientist.

(Cs), in minimum lots of 10 tons delivered to an entry point, at $300 per short ton. At yearend the Metal Bulletin quoted the nominal price for pollucite concentrates containing a minimum 24% Cs_2O, f.o.b. source, at $12.40 to $13 per metric ton unit (22.046 pounds of Cs_2O).

The American Metal Market quotation on cesium metal, 99+% purity remained unchanged at $100 to $375 per pound. The quotation on rubidium metal, 99.5% purity, also remained unchanged at $300 per pound.

Table 4.—Prices of selected cesium and rubidium compounds in 1974

Item	Base price per pound[1]	
	Technical grade	High-purity grade
Cesium bromide	$28	$65
Cesium carbonate	29	67
Cesium chloride	30	68
Cesium fluoride	35	75
Cesium hydroxide	35	75
Rubidium carbonate	45	75
Rubidium chloride	46	76
Rubidium fluoride	51	83
Rubidium hydroxide	51	83

[1] Excludes packaging cost, 50- to 100-pound quantities, f.o.b. Revere, Pa.

Source: Kawecki Berylco Industries, Inc.

Foreign Trade.—Pollucite import data were not available. However, reported receipts by consumers indicate that pollucite was imported. It was likely that most of the pollucite consumed in the United States was imported from Canada.

Imports of cesium compounds increased from 3,159 pounds valued at $111,631 in 1973 to 4,622 pounds valued at $167,965 in 1974. There were no reports of cesium and rubidium metal imports during the year. No other data were available on imports or exports of cesium or rubidium products.

World Review.—In May 1974 Kawecki Berylco Industries, Inc., acquired 24.9% of the stock of the Tantalum Mining Corp. of Canada (TANCO) at Bernic Lake, Manitoba, Canada. TANCO has the world's only commercial source of pollucite. By participation in TANCO operations Kawecki Berylco Industries, Inc., has access to a viable commercial source of raw cesium ore.

Technology.—Increasing scientific and engineering interest in development and commercialization of MHD techniques for electric power generation in the United States and the U.S.S.R. may lead to future commercial use of cesium oxide. In July 1973 the United States and the U.S.S.R. signed a memorandum of understanding for joint research in MHD electric generation.

Germany, West	2,038	$92,495	1,463	59,924
United Kingdom	110	3,523	29	652
Total	2,148	96,018	2,474	71,947

GERMANIUM [5]

Production and consumption of germanium showed no significant changes in 1974 from those since 1970. A few of the domestic consumers designed germanium out of some of their electronic systems, but at the same time, the use of germanium in optics increased to recover that part of the lost semiconductor market.

Domestic Production.—Production of germanium from domestic sources was estimated at 28,000 pounds in 1974. Germanium was a minor byproduct of ores mined for zinc. No new residues were being recovered from the Kansas-Missouri-Oklahoma zinc-bearing region, and no mines were operated solely for recovery of germanium. Recycled waste or new scrap obtained from the manufacture of semiconductors supplemented the domestic supply. In addition, first reduction metal or scrap was imported and refined.

Eagle-Picher Industries, Inc., of Quapaw, Okla., was the sole U.S. producer of primary germanium in 1974. The company extracted germanium from the stockpile of zinc smelter residues at its plant at Quapaw, and it also reprocessed scrap. Other processors of secondary germanium and imported metal were GTE Sylvania Inc., Towanda, Pa.; Kawecki Berylco Industries, Inc., Revere, Pa.; and Atomergic Chemetals Co., Carle Place, Long Island, N.Y. GTE Sylvania discontinued its germanium producing operation at yearend and sold its equipment and technology to Texas Materials Laboratory, Garland, Tex.

Consumption and Uses.—The major end use for germanium has been in semiconductors such as transistors, diodes, and rectifiers. While the overall requirement for semiconductors has increased, the demand for germanium in this end use has declined, as shown in table 6.

Since germanium has a high refractive index, it found its way into numerous optical applications. Germanium is opaque in the visible region of the spectrum but transparent to the infrared region. This property made it useful as windows and lenses. Optical systems containing germanium were used in microscopes, surveillance devices, aerial photography, and medical devices. Specially doped germanium crystals were also used as infrared detectors.

Table 6.—Market estimates of semiconductor shipments

Source: Electronics. U.S. Markets 1975. V. 48, No. 1, Jan. 9, 1975, pp. 82–102.

Germanium was used for gamma ray detection, principally for nuclear research, activation analysis, and medical applications. Germanium was used in various alloys, in brazing or soldering material, in corrosion-resistant, high-strength zirconium alloys, in beryllium alloys to improve ductility, and in gold alloys for precision casting. Some petroleum refining operations and processes for the production of polyester fibers employed germanium catalysts.

Other uses for germanium were in X-ray equipment, fluorescent lamps, strain gages, batteries, superconductor materials, nodular cast iron, and biological organogermanium compounds.

Prices.—The prices of domestic zone-refined (intrinsic) germanium and domestic germanium dioxide were $293 and $167.50 per kilogram, respectively, through 1974. These prices were in effect since June 8, 1970. Imported germanium prices increased on February 1, 1974, to $275 per kilogram for germanium metal and $145.50 per kilogram for germanium dioxide. The previous prices were $260 and $136 per kilogram, respectively.

---

[5] Prepared by Herbert R. Babitzke, physical scientist.

Foreign Trade.—U.S. imports of germanium metal (unwrought, and waste and scrap) totaled 14,099 pounds valued at $1,014,801 in 1974, a decrease in quantity of 4% from that of 1973. Italy supplied 46% of the germanium imports, the U.S.S.R. supplied 20%, and the Netherlands, 11%. The value of imports varied considerably among countries, from $24 per pound in Italy to $1,277 per pound in Belgium-Luxembourg. This suggests that the germanium from Belgium-Luxembourg was high-purity single crystal, while the low-valued material was probably concentrates or scrap.

Table 7.—U.S. imports for consumption of germanium in 1974, by country

Country	Quantity (pounds)	Value
Unwrought, and waste and scrap:		
Belgium-Luxembourg	291	$371,472
France	291	16,638
Germany, West	1,010	59,945
Italy	6,489	158,328
Netherlands	1,540	112,697
South Africa, Republic of	1,074	78,219
United Kingdom	540	48,068
U.S.S.R	2,864	179,434
Total	14,099	1,014,801

World Review.—World production of primary germanium was estimated at 168,000 pounds in 1974. The main producing countries were the United States, Japan, Belgium-Luxembourg, and Italy. No production data were available on a country by country basis.

Technology.—Research continued on the development of organogermanium compounds as polymers and therapeutic agents. Certain compounds showed promise in the treatment of carcinoma and leukemia. Development continued on platinum-germanium catalysts, whose principal use is in the conversion of hydrocarbons, particularly in the reforming of the gasoline fraction.

Progress was made toward the production of a practical columbium-germanium superconductor. A technique called sputtering was used to lay a film of columbium-germanium atoms on a strip of sapphire. The film, only a few thousand atoms thick, retained its superconductivity up to 23.2° K., the highest temperature yet achieved.[6]

Infrared guidance systems were being developed by the U.S. Defense Department. These systems known as FLIR (Forward Looking Infra-Red) allows aircraft, tank, and helicopter gunners to see targets at night and through smoke cover.[7]

Germanium-containing materials were developed for use as optical waveguides. The lowest transmission loss optical waveguides to date are those with a high silica content prepared by vapor deposition. The composition, a core of GeO_2-SiO_2 surrounded by SiO_2 cladding, combines low loss with relatively large index differences between core and cladding.[8]

INDIUM[9]

Domestic Production.—Domestic indium production during 1974 was by American Smelting and Refining Company (ASARCO Incorporated) at its Denver, Colo., plant and by Indium Corp. of America in Utica, New York. Other companies processed or refined imported material to produce high-purity metal components, alloys, and compounds. An appreciable portion of U.S. consumption was contributed by domestic producers, but the major share was from imported metal. A large but unmeasured share of domestic supply came from secondary or scrap materials.

[6] Bishop, J.E. Superconductor Hunt Is Getting Warmer, Bell Labs Aides Say. Wall Street J., v. 183, No. 39, Feb. 26, 1974, p. 36.

[7] Metal Bulletin. No. 5971, Mar. 4, 1975, p. 21.

[8] MacChesney, J.B., P.B. O'Connor, and H.M. Presby. A Technique for the Preparation of Low Loss and Graded-Index Optical Fibers. The Institute of Electrical and Electronics Engineers, Inc., v. 62, No. 9, September 1974, pp. 1278-1279.

[9] Prepared by John M. Hague, mining engineer.

Uses.—The pattern of indium usage was estimated to be divided as follows: 30% in solders, low-melting alloys, and coatings; 30% in instrument applications and holding devices; 18% in electronic components; 6% in nuclear reactor controls; and 16% in research and other uses.

Stocks.—Producer stocks continued to decline, but at a reduced rate; stocks of producers and consumers are estimated to be adequate for short-term requirements.

Prices.—Indium pricing is based on the standard-grade metal, 99.97% pure. Higher purity grades, 99.999% plus, are available at a premium. Since December 1972 the producer quotation published in Metals Week has been for ingots, usually of 100 ounces, in lots of 10,000 ounces or more. The quotation remained at $2 per troy ounce through January, was $2.50 in February and March, $3 in April and May, and was raised to $5.50 per ounce by ASARCO in July, retroactive to May 13. The $5.50 quotation continued to the end of the year for an average price in 1974 of $4.42 per ounce.

Foreign Trade.—Imports of indium in 1974 decreased sharply from the 1973 level. Total imports were 493,000 troy ounces in 1974 compared to 812,000 troy ounces in 1973. Source countries ranked as follows: Canada, 36%; Peru, 21%; Japan, 18%; the United Kingdom, 12%; West Germany, 8%; the Netherlands, 4%; and East Germany, 1%.

The duty on unwrought, waste, and scrap indium has been 5% ad valorem since January 1, 1972 for the most favored nations. Since June 30, 1971, duties on waste and scrap have been suspended until June 30, 1975. The duty on wrought indium was 9%. Statutory duties for the U.S.S.R. and East Germany were 25% ad valorem on unwrought indium and 45% ad valorem on wrought metal.

Imports from the U.S.S.R. apparently did not develop in 1974 as the asking price was above the European free market. Cominco, Ltd., the sole Canadian producer, was the source of supply for over 20% of U.S. demand.

Table 8.—U.S. imports for consumption of indium in 1974, by country

Country	Quantity (troy ounces)	Value
Unwrought, waste and scrap:		
Canada	178,725	$541,801
Germany, East	3,876	9,413
Germany, West	41,073	97,152
Japan	86,939	600,112
Netherlands	19,006	57,909
Peru	102,274	328,015
Switzerland	458	4,551
United Kingdom	59,805	258,765
Total	492,156	1,897,718
Wrought: Canada	822	7,541

Technology.—Photovoltaic solar energy cells being developed by Bell Laboratories use cadmium sulfide deposited either on a substrate of single-crystal indium phosphide or on single-crystal copper indium diselenide. If these cells can be made by thin-film techniques, the cost will be less than current silicon solar cells and may allow large area cells to be made.[10]

RADIUM[11]

During 1974 radium was used mostly in therapeutic treatment of cancer. However, in medical and industrial applications, cheaper and less hazardous radioisotopes continued to replace radium. Cesium radioisotopes have replaced some quantities of radium used for cancer treatment in hospitals throughout the United States.

---

[10] Chemical and Engineering News. Technology. V. 53, No. 7, Feb. 17, 1975, p. 20.

[11] Prepared by Roman V. Sondermayer, physical scientist.

Domestic Production.—There has been no production of radium in the United States since 1950. The small domestic demand was met by imports, withdrawal from dealers' stocks, and reprocessing. Radium Chemical Co., Inc., New York, was the main dealer in the country.

Consumption and Uses.—Small quantities of radium, expressed in milligrams, were used in the treatment of cancer, luminous compounds, static eliminators, and neutron sources. Nearly 5 grams of new radium were sold, and about 900 grams of radium were in use in the United States during 1974. About 90 grams were stored in a Government-owned depository in Alabama. During 1974 129 requests for deposits of 665 radioactive sources, containing about 3,758 milligrams of radium, were received by the Bureau of Radiological Health, U.S. Department of Health, Education, and Welfare.

Substitution of manmade radioisotopes for radium continued during 1974.

Prices.—Radium prices, per milligram, were quoted by Radium Chemical Co., as follows: Less than 100 milligrams, $26.50; 100 to 199 milligrams, $25; 200 to 499 milligrams, $22; over 5 grams, $20.

Foreign Trade.—Data on trade in radium were not published; in most cases, the radium data were included with those for other items in trade statistics. Belgium remained the principal source of radium imported into the United States.

World Review.—Information on radium in world markets was not readily available. The Belgian company, Union Minière S.A., was the largest radium producer and supplier in the market economies. In addition, small quantities of radium were apparently produced in Canada and the United Kingdom. Czechoslovakia, with its long tradition in uranium mining, and the U.S.S.R. probably also produced some radium. Throughout the world, uses of radium were similar to those in the United States.

Technology.—Procedures were established for sequential determination of radium in the environment and in process waste samples at 0.1 down to 0.001 of the guides specified by Federal Regulations.[12]

SCANDIUM[13]

During 1974 scandium was used mostly in research, which, however, did not disclose any major useful property that was not found in less costly and more abundant elements. In the United States one producer provided most of the scandium metal and oxide consumed during the year.

Domestic Production.—There was no scandium mine production in the United States in 1974. Research Chemicals, a division of Nucor Corp., Phoenix, Ariz., remained the only domestic producer of scandium metal and compounds. Output, measured in a few tens of pounds and derived from imported materials, was adequate to meet demand.

Consumption and Uses.—The main industrial applications of scandium were in high-intensity lamps for lighting outdoor events to be televised in color and in radioactive tracers for controlling flow of underground fluids in petroleum production. Small quantities of scandium were also consumed in magnesium alloys and in the electronics and chemical industries. Scandium was used in research which was aimed at a better understanding of its properties and behavior in different environments. Researchers studied scandium radioisotopes and investigated alloying, electrical, and chemical properties of the metal, compounds, and other products.

---

[12] Percival, D.R., and D.B. Martin. Sequential Determination of Radium-226, Radium-228, Actinium-227, and Thorium Isotopes in Environmental and Process Waste Samples. Anal. Chem., v. 46, No. 12, October 1974, pp. 1742-1749.

[13] Prepared by Roman V. Sondermayer, physical scientist.

Prices.—The tabulation below shows prices for scandium metal and oxide quoted by Research Chemicals:

Metal	Per gram, from 1 to 99 grams	Per gram, from 100 to 453 grams
Ingots	$10.50	$8.00
Powder	11.50	10.35
Chips	11.50	10.35
Distilled	19.00	15.00
Oxide:		
99.99%	5.00	4.00
99.9%	3.50	2.80
Salts [1]	2.50	2.00

[1] Salts include acetates, carbonates, chlorides, nitrates, and oxalates in most stable, hydrous form produced from oxides of 99.9% minimum purity.

Foreign Trade.—Official U.S. foreign trade statistics did not report trade in scandium as such but included scandium with other minerals and metals. However, based on available information, Australia and the centrally controlled economies were the principal suppliers of scandium-bearing raw materials.

World Review.—Information on scandium-related activities in foreign countries was not readily available. The industrialized nations were involved in scandium research and used small quantities of scandium in industrial applications.

Technology.—Scandium and the rare earth metals, at concentrations of 0.01 to 0.1 weight percent in uranium matrix alloys, were quantitatively determined by atomic absorption in perchloric acid solution of the alloy without separation. According to Los Alamos Scientific Laboratory scientists, the measurement's standard deviation for scandium at 0.1 wt% and 0.01 wt% was 1% and 5%, respectively.[14]

In another research project, dioctylarsenic acid (HDOAA) in chloroform solution was investigated as a reagent for the extraction of scandium, cerium, europium, and ytterbium trichlorides. The extraction coefficients for these metal ions were sufficiently different to allow their extractive separation.[15]

SELENIUM [16]

Domestic production of selenium from primary materials was 644,000 pounds in 1974, a 19% decrease from the 1973 production of 796,000 pounds.

Shipments by domestic producers decreased 21% to 671,000 pounds. Producer stocks were drawn down by 27,000 pounds and were 79,000 pounds at yearend. The cutback in production and shipments was the result of a 42-day copper strike in Arizona in July and August and decreased demand in the second half of the year. World production remained constant at 2,621,000 pounds.

Under its program to dispose of the national stockpile of selenium, the General Services Administration (GSA) sold 124,442 pounds of selenium during the year and made shipments for consumption of 223,606 pounds. At the end of 1974 the national stockpile contained 8,639 pounds of which less than 2,500 pounds is uncommitted.

^{e} Estimate. ^{r} Revised.

Domestic Production.—In the United States in 1974 selenium was recovered at the following four copper refineries: AMAX Copper, Inc., Carteret, N.J.; American Smelting and Refining Company (ASARCO Incorporated), Baltimore, Md.; Kennecott Copper Corp., Magna, Utah; and The Anaconda Company, Perth Amboy, N.J.

In addition anode slimes recovered from the electrolytic tanks of copper refineries owned by other foreign and domestic mining companies were shipped to these plants for recovery of gold, silver, selenium, and tellurium.

High-purity selenium and various selenium compounds were produced by primary and other processors from commercial-grade metal.

Published estimates of secondary recovery of selenium from xerographic, rectifier, and chemical processes in 1974 of 185,000 pounds include both Canadian and U.S. reclamation.[17] However a large portion of the Canadian secondary production is accounted for by imports of selenium scrap from U.S. markets. Data on actual recovery by domestic secondary refineries were not available but recovery was estimated to have ranged from 30,000 pounds of selenium in 1970 to less than 20,000 pounds in 1974.

ASARCO's new 420,000-ton-per-year electrolytic copper refinery at Amarillo, Tex., was 55% complete at yearend. Completion of the entire facility including a byproduct plant is planned for the first quarter of 1976. The ASARCO Baltimore refinery will be phased out at that time. Anaconda is reportedly considering closing its Perth Amboy copper and byproduct refinery in 1975.

Consumption and Uses.—Apparent consumption of selenium in 1974 consisting of shipments from primary producers, net imports, and stockpile releases was over 1.5 million pounds, an increase of 14% over that in 1973. Demand for selenium began decreasing in the second half of 1974 as the requirements for selenium-bearing glass, pigments, and electronic components were affected by the sharp slowdown in manufacturing and construction activity. Trends in 1974 suggested the following estimate of selenium purchases and consumption by end use categories: Electronic components including xerography, 45%; glass manufacturing, 34%; chemicals, 13%; and other, 8%.

Xerography continues to be a major growth industry for selenium with an estimated 350,000 to 400,000 pounds consumed in 1974. Proposed settlement of an antitrust action by the Federal Trade Commission would require Xerox Corp. to provide know-how and patents to licensees.[18]

In other electronic applications the high demand for selenium in semiconductors used in calculators, photoelectric cells, and in the vidicon television camera continued. Shipments of all types of semiconductors increased about 16% in the United States in 1974 over those of 1973, however, an industrywide slump had begun in the second half of 1974.[19] With lower cost silicon substitutes on the market the production of selenium rectifiers was beginning to decline with a resulting decrease in rectifier scrap available for secondary recycling.

The largest single consumer of selenium

---

[17] Baltrusaitis, V.A. Selenium-Tight Supplies Ease Up at End of '74. Eng. and Min. J., v. 176, No. 3, March 1975, pp. 153-155.

[18] The Wall Street Journal. IBM Attacks FTC Proposed Settlement of Antitrust Complaint Against Xerox. V. 185, No. 2, Jan. 3, 1975, p. 18.

[19] The Wall Street Journal. After Bad 2nd Half, Semiconductor Firms See More of Same for Much of This Year. V. 185, No. 2, Jan. 9, 1975, p. 26.

continued to be the glass manufacturing industry, although selenium is somewhat vulnerable to substitution by the rare earth, cerium oxide. Selenium is added in amounts of 0.02 to 0.3 pound per ton of glass to neutralize the green iron discoloration. Dark-colored selenium glass used in office windows to reduce glare and heat transfer is finding a growing energy conservation application.

In its major use in the industrial chemical field cadmium sulfoselenate compounds are used widely as heat-resistant red pigments in plastics, paints, inks, and enamels. The expansion of new pharmaceutical preparations saw consumption in this area increase to about 50,000 pounds of selenium in 1974.

Demand for selenium in other end uses included the addition of small amounts of ferroselenium to improve the casting, forging, and machining characteristics of stainless steel. There are also minor applications for elemental selenium and selenium diethyldithiocarbamate in the processing of natural and synthetic rubber. In February 1974 the Federal Food, Drug, and Cosmetic Act was amended to allow the maximum addition of 0.1 part per million of sodium selenite to premixed chicken and swine feeds and 0.2 part per million to premixed turkey grain feeds as a nutrient to control diseases and to increase production.[20] As the practice becomes widespread, it is estimated that annual consumption will be 13,000 pounds.

Stocks.—GSA essentially completed its disposal of the national stockpile of selenium during 1974. The combination of a record high consumption and the copper industry strike reduced producer stocks to the equivalent of 2 weeks' domestic demand in the second quarter. Reduced demand in the fourth quarter allowed producers to start rebuilding inventories which totaled 79,000 pounds on December 31, 1974. The high apparent consumption in 1974 is attributed in part to manufacturers buying ahead to cover future requirements. Japan, the world's largest producer of selenium, built up large stocks of unsold selenium during the second half of 1974. The overhang of excess Japanese stocks on the world market contributed to weakened price levels.[21]

Prices.—Selenium is usually sold as commercial-grade powder containing 97% to 99.94% selenium or as high-purity grade in pellets, sticks, and rectifier shot containing 99.95% to 99.99+% selenium. Pellets containing 99.999+% selenium are available. Domestic producer prices for commercial and high-purity grades increased from $11 and $14 per pound, respectively, in January 1974 to $15 and $18 per pound in March. A further increase in May raised prices to $18 and $21 per pound. Merchant prices for commercial-grade selenium increased from $17.50 per pound in January to a high of $37.50 in June, but by the end of the year prices had slipped to $11 to $13 per pound.

Merchant prices generally responded to high and low demand pressures during the year. The producers price however, showed a steady upward trend.

Foreign Trade.—The U.S. Department of Commerce reported selenium exports separately for the first time in 1974.[22] Exports of selenium metal in 1974 totaled 166,206 pounds, valued at $2,013,322, with an average value of $12.11 per pound. Shipments to West Germany (30%), the Netherlands (16%), Belgium (13%), the United Kingdom (12%), Australia (6%), Canada (4%), and France (4%) accounted for the majority of all exports with the remainder exported in lots of 6,000 pounds or less to 13 other countries.

[21] Metals Week. V. 45, No. 48, Dec. 2, 1974, p. 7.

[22] U.S. Department of Commerce. Foreign Trade Statistics. Classification of Exports. Sec. 5. Chemicals. Schedule B, Selenium Metal, code 513.290, 1974.

Selenium imports for consumption increased 51% to 837,191 pounds and the value of imports increased 88% over that of 1973 to $10,555,973. The average value of unwrought, waste and scrap selenium imported during the year was $12.74 per pound and for selenium dioxide $10.42 per pound. Canada supplied 87% of all selenium imported, with the remainder coming from Japan (5%), Belgium (3%), Norway (2%), and nine other countries (3%). In addition to the above, 712 pounds of selenium salts valued at $18,105 and 3,356 pounds of unspecified other selenium compounds valued at $36,827 were imported into the United States in 1974.

U.S. tariff schedule items 632.40, selenium metal, unwrought, other than alloys and waste and scrap; 420.50, selenium dioxide; and 420.52, selenium salts; were duty free at yearend. The duty on item No. 420.54, other selenium compounds, was 5% ad valorem.

Table 11.—U.S. imports for consumption of selenium in 1974, by country

(Thousand pounds and thousand dollars)

[1] Less than ½ unit.

World Review.—In 1973 the United States continued as the leading selenium producer, followed by Japan. In 1974 Japan was the leading producer with an output of 800,000 pounds. In both years Canada was the third largest producer. These three countries accounted for 81% of world selenium production in 1973 and 78% in 1974.

Canada.—Selenium production from primary raw materials has decreased since 1971 as an increasing amount of copper production from Canadian mines is derived from selenium-poor ores. The major selenium producers, Canadian Copper Refiners Ltd. and The International Nickel Co. of Canada, Ltd. with annual capacities of 500,000 pounds and 180,000 pounds of selenium, respectively, were unable to meet demand from primary production in 1973 and 1974. In 1973 exports to all countries exceeded primary production by 242,000 pounds and in 1974 by 337,000 pounds. In 1973 Canada consumed only 22,000 pounds of selenium domestically.

Japan.—Japan continued to import large tonnages of copper concentrates under long-term contract arrangements with producers in Australia, Canada, and Latin America which ensured it of large supplies of raw selenium-bearing materials. During periods of depressed market conditions such as occurred in both copper and selenium in late 1974 the Japanese continued to refine the copper and associated slimes in order to keep on top of the fixed volume of raw materials flowing into the country.

Table 12.—Selenium: World refinery production, by country[1]
(Thousand pounds)

Country	1972	1973	1974 [p]

Total	[r] 2,721	2,626	2,621

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Insofar as possible data relate to refinery output only; thus countries that produce selenium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but do not recover refined selenium are excluded to avoid double counting.

[2] Net exports (exports minus imports).

[3] Refinery output from all sources, including imports and secondary sources.

[4] Recoverable selenium content of the blister copper treated at domestic refineries, plus refined selenium from domestic primary material.

Technology.—A U.S. patent was issued on a solvent extraction process used to recover selenium from an aqueous, offgas scrubber solution from the roasting of molybdenite. The process uses a tertiary amine to extract metal values. Molybdenum and rhenium values are stripped with aqueous sodium carbonate and then selenium values with an aqueous solution of ammonium hydroxide or sodium sulfite.[23]

As an offshoot of research to develop an organic material that would be a superconductor at or above room temperature, a new crystal has been designed by replacing sulfur atoms with selenium atoms in a solid organic crystal. The new crystal conductor is one of the most electrically conductive organic metals so far reported and retains this behavior at lower temperatures (40°K) than any other material.[24]

Baltrusaitis,[25] also noted that a European battery manufacturer has developed a lead-selenium alloy which helps to eliminate gas discharge and reduces antimony requirements. In this application, selenium is being tested in competition with calcium for performance in maintenance-free batteries.

A comprehensive reference book on selenium was published in late 1974 covering the history, occurrence, extraction, properties, biochemical and agricultural aspects, toxicology, analytical chemistry, and five chapters on end use applications.[26]

TELLURIUM[27]

Domestic tellurium production of 191,000 pounds in 1974 was 21% below that of 1973. The primary producers shipped 157,000 pounds of tellurium to consumers in 1974, a decrease of 45% from 1973. Producer stocks increased 55% to 87,000 pounds. The level of imports increased 131% to a record high of 164,000 pounds in 1974.

r Revised.

Domestic Production.—Tellurium was recovered as a byproduct of electrolytic copper refining by: AMAX Copper, Inc., Carteret, N.J.; American Smelting and Refining Company (ASARCO Incorporated), Baltimore, Md.; and The Anaconda Company, Perth Amboy, N.J. Commercial grade tellurium was produced from the precious-metal-rich anode slimes shipped from other domestic copper refinery tankhouses. High-purity tellurium, tellurium master alloys, and tellurium compounds were produced by primary and intermediate processors from commercial-grade metal and tellurium dioxide. Lower production of tellurium in 1974 was attributed to a combination of the copper industry strike in July and August and lower tellurium content of ores being mined. Construction of ASARCO's new copper and copper byproducts refinery in Amarillo, Tex., was on schedule and startup is expected in early 1976 at which time the Baltimore facility will be phased out. Anaconda was reportedly considering closing its Perth Amboy refinery in 1975.

Consumption and Uses.—Apparent consumption of tellurium for the year as indicated by producer shipments to consumers and imports for consumption decreased 10% to 321,000 pounds from 1973. The decrease can be related to the general slowdown of the U.S. economy, particularly in the second half of the year. Manufacturers were working off inventories and there was less consumer buying of the iron, steel, and copper products which consumed most of the tellurium. Tellurium consumption by end use in 1974 was estimated as follows: Iron and steel production, 70%; nonferrous metal production, 19%; chemical uses, 6%; and other uses including rubber manufacturing, 5%. Tellurium is used in its elemental state as a free-machining agent in stainless steel and copper production, in the chilling of malleable cast iron, and as a curing agent and accelerator in rubber compounding. Bismuth and lead telluride alloys are used in semiconductor and minor thermoelectric applications. Tellurium is used in the dioxide state in the forming and tinting of glass and as a chemical catalyst. Applications for tellurium are somewhat limited by the relatively small availability of refined material and by price. These factors make tellurium susceptible to substitution, particularly by lead which exhibits many of the same machining properties as tellurium. Selenium and sulfur can substitute for tellurium in rubber compounding and selenium also substitutes in some semiconductor applications.

Stocks.—Producers began to rebuild stocks in 1974 adding 31,000 pounds to the abnormally low 1973 stocks of 56,000 pounds. In addition to inventories of refined tellurium there are available stockpiles of crude materials and impure intermediate tellurium products which are accumulated for refining as needed. There is no tellurium in the U.S. Government stockpile.

Prices.—The producer price for commercial-grade powder and slab was $7 per pound until May 1 when the price was increased to $9 per pound which remained firm for the remainder of the year. Noranda Mines Limited raised the Canadian producer price to $10 per pound on November 29, 1974, however, the U.S. producers did not follow this change. Prices for high-purity tellurium ranged from $10 to $32 per pound depending upon quality and quantity.

Tellurium is usually marketed in the form of minus 200-mesh powder or as slabs, tablets, or sticks. Normal commercial grades contain a minimum of 99% or 99.5% tellurium. Further refining through distillation and sublimation processes produces high-purity grades chiefly for use in semiconductors containing 99.95%, 99.999%, and 99.9999% tellurium.

Foreign Trade.—Imports of tellurium for consumption in the United States in 1974 were the highest on record, totaling 164,000 pounds, 131% higher than in 1973 and 73% higher than the average imports during 1970–74. Canada supplied 72% and Peru 22% of all imports.

The 1974 U.S. tariff on TSUS Item No. 632.48, tellurium metal, unwrought, other than alloys, and waste and scrap was 4% ad valorem and TSUS Items No. 421.90, tellurium compounds and 427.12, tellurium salts was 5% ad valorem. The statutory tariff on these items was 25% ad valorem. There are no data on tellurium exports.

Table 14.—U.S. imports for consumption of tellurium in 1974, by country

(Thousand pounds and thousand dollars)

Country	Quantity	Value
Unwrought, waste and scrap:		
Canada	118	1,224
Germany, West	(1)	1
Japan	6	41
Peru	36	289
United Kingdom	4	26
Total	164	1,581

[1] Less than ½ unit.

World Review.—The United States continued as the world's largest producer and consumer of tellurium. In 1974 the United States produced 53% of all new refined tellurium while the U.S. apparent consumption was 90% of total world production of 362,000 pounds. The balance of world tellurium output in 1974 was nearly equally distributed among Peru, Japan, and Canada.

Fiji.—The Emperor Gold mine at Vata Koula, Fiji, was scheduled to increase annual tellurium production to 40,000 pounds, but no detailed production figures are yet available. This would make the Emperor Gold mine the world's largest tellurim producer.[28] Emperor has reportedly developed a new telluride leaching process which improves the economic feasibility of extracting tellurium from gold telluride resources, and which could encourage the further production of tellurium from similar deposits in Colorado and elsewhere in the world.

Total	r 396	446	362

e Estimate. p Preliminary. r Revised.

[1] Insofar as possible data relate to refinery output only; thus countries that produce tellurium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but do not recover refined tellurium are excluded to avoid double counting.

[2] In addition to the countries listed, Australia, Belgium, West Germany, and the U.S.S.R. are known to produce refined tellurium, and other major copper refining nations such as Chile, Zaire, and Zambia may produce refined tellurium but production is not reported and available information is inadequate for formulation of output level estimates.

[3] Refinery output from all sources, including imports and secondary sources.

[4] Recoverable tellurium content of blister copper, not necessarily recovered in year designated, plus refined tellurium from domestic primary metal.

Technology.—Copper metallurgy is likely to be modified or changed to minimize smelter air pollution, but it is uncertain what the effect will be on tellurium and selenium recovery. A change to low-pollution furnaces that capture a much greater proportion of effluents would increase the quantity of byproduct tellurium available, while a change to in situ leaching and other hydrometallurgical methods for treating copper ores and concentrates would reduce the recovery of tellurium.

THALLIUM [29]

Thallium is a highly toxic metal that is limited in production, use, and size of market.

Domestic Production.—The only domestic producer of thallium and thallium compounds was the Globe plant of the American Smelting and Refining Company (ASARCO Incorporated) of Denver, Colo. The company recovered thallium as a byproduct from flue dusts and residues of base metal ore smelting, principally zinc. Production of metal and compounds in 1974 was about 1% of that of 1973. Shipments remained about the same.

World Reserves.—Domestic and world reserves of thallium in lead, zinc, and iron sulfide ores were 266 and 1,390 tons, respectively. World resources of thallium, not economically extractable or undiscovered, in zinc and lead sulfides were estimated at 21,672 tons.[30]

Uses.—The United States consumes a very small fraction of total world production. Formerly, the principal use of thallium was a rodenticide. Since 1972 thallium has been banned by Federal edict for all domestic pesticide use. The current uses for thallium are for certain specialized electronic components, pharmaceuticals, agriculture, and for experimental purposes.

Prices.—The price of thallium in 25-pound lots has been $7.50 per pound since December 1957.

Foreign Trade.—U.S. imports for consumption in 1974 were 1,022 pounds of unwrought, and waste and scrap thallium valued at $4,644 and 404 pounds of compounds valued at $4,308. The amount was almost twice that imported in 1973 which totaled 541 pounds valued at $1,730.

•

Table 16.—U.S. imports for consumption of thallium in 1974, by country

Country of origin	Compounds (gross weight)		Unwrought, and waste and scrap	
	Pounds	Value	Pounds	Value
Belgium-Luxembourg	50	$813	25	$370
Canada	--	--	4	778
Germany, West	253	3,042	--	--
Netherlands	101	453	--	--
U.S.S.R	--	--	993	3,496
Total	404	4,308	1,022	4,644

World Review.—World production of thallium is approximately 30,000 pounds annually. In addition to the United States, other major producers of thallium metal and compounds were Belgium, West Germany, and the U.S.S.R.

Technology.—Experiments with high-pressure mercury vapor lamps containing thallium iodide continued. One worker produced a mercury vapor light with a wider spectrum than fluorescent light and a 50% improvement in light intensity over conventional mercury lamps.[31] A new film emulsion containing thallium lead, or gold azides capable of performing under extremely cold conditions prevalent in space was developed for the U.S. Army.[32]

Use of thallium to change the refractive index of glasses continued to be an area of experimentation.[33]

The first known occurrence in gold ore of lorandite, $TlAsS_2$ was discovered in Nevada. The mineral, which contains an average of 60% thallium, was apparently part of the late-stage mineralization of the gold ore.[34]

GREENSAND[1]

The only U.S. producer of greensand (glauconite) in 1974 was the Inversand Co. at Clayton, N.J., which is a subsidiary of Hungerford & Terry, Inc. Information on production and sales is withheld by the Bureau of Mines to avoid disclosing individual company data.

Greensand was used by the parent company in its line of water conditioning equipment. The finer fraction of the material produced, which is unsuitable for water conditioning, was screened out, dried, and sold as a soil conditioner.

The Delaware Geological Survey, in cooperation with the Federal Bureau of Mines, continued its investigation of possible uses for greensand. It was found that the material tested has the capacity to lower the content of many heavy metal contaminants in industrial waste waters. Concentrations of arsenic, cadmium, chromium, copper, lead, silver, and zinc were greatly decreased; it was found that these metals can be easily released back into distilled water, suggesting that the cations are adsorbed on the surface of glauconite pellets, rather than exchanged within the glauconite crystal structure.[2]

IODINE[3]

The world iodine picture changed drastically during 1974. At the beginning of the year, the market was still sluggish and stocks were fairly high. By yearend, demand was up sharply and a long-term shortage was forecast. Prices moved upward from between $2.06 and $2.27 per pound of iodine to $2.40 and $2.59. The Japanese were considering raising prices further to $2.90. U.S. imports during the first 9 months of 1974 were as much as the full-year imports in 1972 and 1973. As in the past, imports from Japan and, secondarily, Chile far exceeded domestic production. The sole U.S. producer—The Dow Chemical Co.—had the longest strike in its history, but output remained at the 1973 level. Late in the year, a joint venture of Pittsburgh Plate Glass Co. (PPG) and Amoco Oil Co. announced plans to develop high-grade iodine brines at Woodward, Okla., for production by yearend 1976. Ethyl Corp. also announced the discovery of similar brines nearby and may be seriously considering future exploitation.

Japan continued to dominate the world scene despite ground subsidence and relocation problems. Production in 1974 was down 9% from the more than 16 million pounds produced in 1973. An upswing was not expected until 1976 or later, which explains why increasing world shortages might be in the offing during the next 2 years. The Chilean iodine situation became more stable with the improved internal situation, and resumption of shipments to the United States to previous high levels might be expected.

[3] Prepared by K. P. Wang, supervisory physical scientist.

Legislation and Government Programs.—On December 31, 1974, the Government strategic stockpile contained 8,011,814 pounds, exactly the same quantity as a year earlier. The stockpile objective for iodine was reduced to zero in early 1973. However, without congressional approval, no iodine withdrawals were possible.

Domestic Production.—Dow Chemical continued to recover crude iodine from well brines at Midland, Mich., as a coproduct with bromine, calcium and magnesium compounds, and potash. A nearly 6-month strike ended in early September. Production did not suffer because "salaried" workers manned the operations.

Table 1.—Crude iodine consumed in the United States

Products	1973			1974		
	Number of plants	Crude iodine consumed		Number of plants	Crude iodine consumed	
		Thousand pounds	Percent of total		Thousand pounds	Percent of total

Organic compounds	19	r 2,439	r 42	23	2,517	41
Total	[1] 32	r 5,755	100	[1] 33	6,075	100

r Revised.

[1] Nonadditive total because some plants produce more than one product.

Consumption and Uses.—Based upon a Bureau of Mines canvass, approximately 6.1 million pounds of crude iodine was consumed by 33 firms in 14 States. Leading iodine-consuming States in 1974, in descending order of magnitude, were Missouri, New Jersey, New York, and Pennsylvania, which together accounted for three-fourths of the total crude iodine consumption.

The canvassed information is indicative of the consumption pattern but is not necessarily all inclusive. Iodine and iodides used as catalysts and in "dissipative" uses in general, particularly in making synthetic rubber, are not well covered. Imports alone have been consistently higher than reported consumption, with net differences as follows, in thousand pounds: 1970–981; 1971–2,473; 1972–949; 1973–348; and 1974–1,895. Real consumption of iodine in the United States may have been closer to 7 million pounds in 1974.

Iodine consumed in making immediate downstream products, such as resublimed iodine, potassium iodide, sodium iodide, and organic iodine-containing compounds have increased slightly in recent years for most items. As for ultimate downstream uses, the major categories for 1974 were roughly as follows: Catalysts (that is, in rubber) 20%; food supplements (animal and fowl feed, mainly for cattle), 15%; stabilizers (that is, in nylon), 15%; inks and colorants, 15%; pharmaceuticals, 15%; and sanitary uses, 10%. Iodine was also consumed in making high-purity metals, motor fuels, iodized salt, photographic chemicals, smog inhibitors, and lubricants.

Prices.—Japan and Chile both raised iodine prices from $2.27 a pound to $2.59 in September. Japan did so primarily because of increases in energy costs, and Chile followed suit. Also, world demand exceeded supply late in the year. Dow Chemical held its iodine price at $2.40 per pound. Quoted U.S. prices for iodine and iodine compounds at yearend 1974 were as follows:

	Per pound
Crude iodine, drums	$2.40–$2.59
Resublimed iodine, U.S.P., drums, f.o.b. works	4.00– 5.10
Calcium iodate, drums, delivered	2.50– 2.80
Calcium iodide, 35-pound drums, f.o.b. works	5.98
Potassium iodide, U.S.P., crystals, drums, 1,000-pound lots, delivered	3.45– 3.98
Sodium iodide, U.S.P., crystals, 300-pound drums, freight equalized	3.50– 3.91

Source: Chemical Marketing Reporter.

Foreign Trade.—Crude iodine imported into the United States in 1974 rose 30% in quantity compared with that of 1973, and total value increased 40%. The average value of imported crude iodine rose from $1.72 per pound in 1973 to $1.86 in 1974. About 7.97 million pounds of crude iodine was imported, 81% from Japan and 19% from Chile. In a shortage situation, Chilean iodine was much more easily sold in the U.S. market than a year earlier. Imports of resublimed iodine were nominal as compared with imports of crude iodine.

Tariff rates were 8 cents per pound on resublimed iodine and 12 cents per pound on potassium iodide; crude iodine enters the United States duty free.

Table 2.—U.S. imports for consumption of crude iodine, by country
(Thousand pounds and thousand dollars)

r Revised.

World Review.—*Chile.*—Production of crude iodine in 1974 as a byproduct of nitrates probably exceeded 2,500 tons, compared with a reported 2,435 tons in 1973. These tonnages reflect the combined capacities of existing facilities. Under Chile's new Government, sales were being pushed, and a program to increase production of nitrates and iodine has been initiated. Shortage of capital funds, however, may delay completion of expansion projects that have been designed to increase capacities by possibly one-fourth.

Chile's three iodine plants (and corresponding three nitrate mines)—Pedro de Valdivia, Maria Elena, and Victoria—were all owned by Sociedad Química y Minera de Chile, S.A. (SOQUIMICH). During 1974, the nitrate capacity for Valdivia, Elena, and Victoria was approximately 500,000 tons, 300,000 tons, and 150,000 tons, respectively. Thus, Valdivia's iodine production probably was slightly larger than the other two combined. Valdivia remained unable to produce as much iodine as it could prior to a major fire in late 1971.

Chile regained some of its previously lost market in the United States, partly because of the strong demand. Its pricing policy in 1974 was to follow Japanese quotations. During the first half of 1974, Chile shipped about 250 tons of iodine to the United States and 1,450 tons elsewhere.

China, People's Republic of.—China's iodine output remained small, probably coming from operations in Amoy (Fukien Province), Peihai (Kwangsi Chang Province), and Yuncheng (southern part of Shansi Province). Sizable imports were necessary. Shipments from Chile to China probably have been about 660,000 pounds of iodine annually. During 1974, Japan exported 22,000 pounds of iodine to China, compared with 64,000 pounds in 1973.

Indonesia.—Japanese firms have made serious efforts to develop iodine-bearing brackish waters in Indonesia. Ise Chemical Industries, Ltd.'s joint venture with Mitsui & Co. Ltd. and the Indonesian Government had a tentative target to produce possibly 1 million pounds of iodine annually in a few years' time.

Japan.—Japan continued to be the world's leading iodine producer by far during 1974. Its output of about 7,327 tons of crude iodine, a 9% decline from the 8,038 tons produced in 1973, was still nearly three times that of Chile, the world's second largest producer. The bulk of the Japanese production was exported, approximately half to the United States, which took 3,233 tons in 1974. Japan's other important iodine markets included European Community countries, India, Switzerland, the U.S.S.R., and Canada.

Natural gas brines are the source of Japan's iodine. Eighteen plants owned by five manufacturing groups provided the entire output. All iodine plants, except for one in Niigata, are located around Kuhikurihama on Chiba Peninsula. About two-thirds of the plants are fairly old. Ise Chemical, with half of the country's iodine capacity and most of the better plants (seven in all), continued to operate near optimum capacity. Six other firms, headed by United Resources Co., produced iodine. Half of the plants of these latter companies were having ground subsidence difficulties related to withdrawal of brines and failure to pump adequate solutions back.

In 1973–74, Japan's environmental agency, the Ministry of International Trade and Industry, and Chiba Prefectural authorities started to implement various measures to control ground subsidence, such as discouraging construction of new wells, abandonment of inefficient operations, mandatory recycling of water, and planned discharge of waste solutions. The immediate consequence of these measures was reduced iodine output. At yearend 1974, it became apparent that more than a 10% drop in production might be expected in the coming year. To adjust to these circumstances, all Japanese iodine producers were searching for new raw material sources in places like Niigata, Okinawa, Miyazaki, and Indonesia, even though the grade of brines in these areas may not measure up to the 80- to 100-parts-per-million quality brines of Chiba.

Japan has traditionally set the price of iodine at levels that the traffic can bear without turning to substitutes. However, several significant developments in 1973–74 have cut down on profitability for Japanese iodine producers. Weakening of the Japanese yen meant higher prices in terms of U.S. dollars. Labor costs rose sharply for iodine operations in 1974, and energy costs more than doubled. This explains why the Japanese were thinking of raising prices further with the expectation that the iodine shortage situation would persist.

U.S.S.R.—Soviet iodine production, derived from operations in the Neftechlinski, Black Sea, and Baku areas, probably was in the range from 3 to 4 million pounds in 1974. Supplementary imports were necessary. During 1974, Japan iodine exports to the U.S.S.R. were about 198,000 pounds, compared with 330,000 pounds in all of 1973.

LITHIUM [4]

Domestic output of lithium minerals and lithium carbonate, combined, increased 3% over that of 1973. Estimated total value of domestic lithium production, in the form of lithium carbonate and mineral concentrate, was approximately $35 million. Estimated world supply was 8,000 tons as contained lithium. The United States continued to produce and consume over one-half of the world's lithium supply. The Soviet Union continued as the only other significant producer of lithium compounds from indigenous minerals. Receipts of U.S.S.R.-produced lithium chemicals by selected market economy countries decreased 30% to 452 tons of contained lithium. No new major producers emerged in the world.

Total recorded imports of lithium mineral concentrate by the United States and countries of the European Economic Community decreased 24% to 26,756 short tons, with an estimated lithium content of approximately 500 tons. U.S. imports of lithium minerals decreased by nearly one-half of 3,165 tons. It was stated that any ending of United Nations sanctions on Rhodesian exports of lithium minerals would significantly improve the world supply and affect the world market.

Japan and Western European countries, including West Germany, the United Kingdom, France, and others continued to produce lithium chemicals from lithium minerals, and from lithium carbonate and hydroxide imported primarily from the

---

[4] Prepared by H. B. Wood, geologist, and R. H. Singleton, physical scientist.

United States and the U.S.S.R. Japanese imports of lithium chemicals increased 9% to 686 short tons lithium content. West German imports of lithium chemicals decreased 28% to 476 short tons lithium content. Reported West German exports of lithium chemicals decreased 31% to 238 tons of contained lithium. U.S. exports of lithium chemicals were not completely reported, but apparent exports (recorded imports from the United States by trading partner countries) increased 5% to 810 tons lithium content.

Construction began at Kings Mountain, N.C., of a new 6,000-ton-lithium-carbonate plant which was scheduled for completion in late 1976. In Canada, it was announced that construction of a 5,000-ton-lithium-carbonate plant near Bernic Lake would be completed by early 1977. The combined output of these two plants would increase the world supply of lithium by approximately one-third.

Legislation ad Government Programs.—The General Services Administration (GSA) sold 2,622 short tons of lithium hydroxide monohydrate during 1974. At yearend, 2,918 tons of lithium hydroxide monohydrate were held by GSA under the Federal Property Act.

Domestic Production.—The two major lithium producers, Foote Mineral Co. (Foote) at its Kings Mountain mine and Lithium Corp. of America (Lithcoa) at its Hollman-Bean mine continued to mine and beneficiate spodumene from pegmatite dikes in North Carolina. Reserves were reported to be sufficient for at least 50 years at the current rate of production. Foote continued to recover lithium carbonate from subsurface brines at Silver Peak, Nev., where it increased its capacity to about 7,500 tons per year. Lithcoa was wholly owned by Gulf Resources & Chemical Corp., and 35% of Foote was owned by Newmont Mining Corp. Kerr-McGee Corp. produced a small quantity of lithium carbonate as a byproduct from processing Searles Lake brines for trona near Trona, Calif.

Foote began construction of a 6,000-ton-per-year lithium carbonate plant at Kings Mountain, N.C. It was anticipated that production at this facility, utilizing the sulfate process for winning lithium carbonate from spodumene, would begin late in 1976.

Lithcoa continued to lead the world in production of lithium chemicals and metal. Output totaled 13,000 tons lithium carbonate equivalent (2,400 tons lithium content) of chemicals and some lithium metal at its Bessemer City, N.C. plant. The plant processed all of the spodumene produced at their mine and also spodumene concentrate purchased from Foote's Kings Mountain mine, as well as lithium hydroxide from the GSA stockpile. Lithium chemicals were also manufactured by Foote from North Carolina spodumene and GSA-stockpile lithium hydroxide at Frazer, Pa., Sunbright, Va., and New Johnsonville, Tenn.

Consumption and Uses.—Apparent consumption in the United States continued to increase; consumption was 18% higher in 1974 than in 1973. The major chemical, lithium carbonate, was used primarily as an additive to molten electrolyte in aluminum reduction cells, mainly in the United States, to increase electrical efficiency and reduce fluoride emissions. Although domestic use in this new application doubled during the past 3 years, only about one-third of domestic aluminum potlines used lithium. Other uses for lithium carbonate included porcelain enamels, glasses, glazes, glass ceramics, and pharmaceuticals. The Federal Drug Administration approved the use of lithium carbonate as a prophylaxis for the depressive state of manic-depressive illness.

Lithium hydroxide remained the second most important chemical product. Its main use, production of multipurpose heavy-duty greases, increased moderately. About one-half of domestic greases utilized lithium stearate as a thickener. Use of lithium hydroxide as an additive to electrolyte in alkaline primary batteries continued. Use of lithium bromide and chloride for domestic adsorption airconditioning remained essentially static. Lithium chloride, used to make lithium metal, remained the third most important chemical. Use of lithium fluoride and chloride as a flux in welding and brazing continued, as did use of lithium hypochlorite as a bleach and swimming pool disinfectant. Growth in the use of lithium organic catalysts, primarily butyllithium, was modest, primarily because butyllithium was geared to production of synthetic rubber for automotive use. Use of lithium metal in battery manufacture and organic-synthesis catalysis increased.

The domestic use of low-iron lithium mineral concentrates, as well as lithium carbonate, as substitutes for low-iron petalite ores previously imported from Rhodesia, in the production of low-expansion thermal-shock-resistant ceramics and other specialized ceramics continued to grow.

Demand for lithium compounds in dyes, paints, and resin catalysts increased significantly. Approximately 20% of lithium chemical sales were for products developed since 1970.

Prices.—The domestic price of ceramic-grade spodumene concentrate rose by approximately 40% to $123.50 per ton at yearend as reported in Ceramic Industry. Domestic prices of lithium carbonate and lithium hydroxide monohydrate, the two predominant chemicals, increased by approximately 40% to 79 cents and 87 cents per pound, respectively. The average price for exported lithium hydroxide monohydrate was 93 cents per pound. The domestic price of lithium metal, delivered in 1,000-pound lots, increased 15% to $9.38 per pound at yearend. An increase in demand for lithium carbonate by the aluminum industry was primarily responsible for the major price increases.

Foreign Trade.—United States exports of lithium chemicals are not completely reported in available trade data, with some of the compounds included inseparably with other non-lithium-bearing compounds. However, review of data on imports of lithium compounds from the United States by other countries indicated that in terms of lithium content, lithium carbonate accounted for nearly three-quarters of these exports in 1974, the remainder being largely lithium hydroxide. Japan, West Germany, and France received over 90% of apparent U.S. exports of lithium products. Apparent exports to Japan increased 17%. Trade data wth the United Kingdom were not available. Approximately 1,500 tons of spodumene concentrate, containing an estimated 40 tons of lithium, was shipped to West Germany, France, Belgium–Luxembourg, and the Netherlands, an increase of 23% over 1973.

Imports of lithium-mineral concentrate was one-half of the 1973 level at 3,165 tons and equaled less than 2% of total domestic lithium mine production capacity. Brazil supplied 75% of the imports primarily as hand-picked petalite for use in low-expansion ceramicware; the balance was spodumene concentrate from Canada.

Table 3.—U.S. imports for consumption of lithium mineral concentrate by country of origin and U.S. customs district

[1] Only in the case of lithium hydroxide are U.S. exports of lithium chemicals reported separately in official U.S. trade statistics. Lithium metal exports are also reported in a basket category. Data in this table are derived from import statistics of major trading partner countries.

[2] Officially recorded U.S. exports totaled 522 short tons, distributed as follows: Australia—26, Canada—24, Chile—5, Colombia—13, France—184, West Germany—38, India—5, Indonesia—16, Italy—3, Japan—107, Mexico—43, Netherlands—5, New Zealand—7, Pakistan—3, Philippines—27, the Republic of South Africa—11, Spain—5, and the United Kingdom—less than ½ unit.

[3] Less than ½ unit.

[4] Officially recorded U.S. exports totaled 599 short tons, distributed as follows: Argentina—5, Belgium-Luxembourg—2, Bolivia—2, Brazil—2, Canada—23, France—124, West Germany—55, India—2, Indonesia—6, Italy—20, Japan—181, the Republic of Korea—1, Mexico—21, the Netherlands—56, Romania—5, Spain—36, Sweden—less than ½ unit, and the United Kingdom 58.

[5] Reported as lithium bromide plus potassium bromide; 50% of total assumed to be lithium bromide.

World Review.—*Brazil.*—Brazil's potential as an important source of glass- and ceramic-grade lithium ores was further explored by Companhia Estanifera do Brazil, and 29 outcrops have been discovered in the province of Minas Gerais. Small amounts of handpicked ore were produced for domestic consumption in manufacture of black-and-white television tubes. A few thousand tons of handpicked petalite ore was exported to Corning Glass Works in the United States, one-third less than in 1973. Brazil produced approximately 50 tons of lithium carbonate from the mineral amblygonite.

Canada.—Successful operation of a pilot plant by Tantalum Mining Co. (Tanco) at Bernic Lake, Manitoba, demonstrated a method for producing a low-iron (0.1% Fe_2O_3) spodumene concentrate suitable for the ceramics and specialty market. A lower grade lithium byproduct was found suitable as feedstock for a lithium carbonate plant. Plans were announced to build, by early in 1977, a facility with an annual capacity of 5,000 tons of lithium carbonate and 1,500 tons of low-iron spodumene concentrate. Kawecki Berylco Industries, Inc., of New York acquired a 24.9% interest in Tanco in May. The largest previously known Canadian mine, Canada's only significant past producer, located in the Val d'Or-Amos area of Quebec, remained closed pending further price increases on the world market. A small amount, 800 tons, of spodumene concentrate was exported to the United States, a fourfold increase over that of 1973.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, others (notably the U.S.S.R.) may produce lithium minerals, but available information is inadequate to make reliable estimates of output levels.

[2] U.S. imports from listed producing countries.

[3] Official import statistics of trading partner countries reported significantly higher imports of lithium-bearing minerals from Mozambique than were reportedly produced in that country. The excess is presumably of Southern Rhodesian origin.

[4] Output has not been reported since 1964, but presumably has continued at a reduced level. Lithium minerals reported produced in 1964 were petalite, lepidolite, spodumene, and eucryptite.

[5] Output has not been reported since 1966, but presumably has continued, inasmuch as a number of countries record imports from "South Africa" which in total considerably exceed reported output of the Republic of South Africa. Estimates given represent total reported imports from South Africa by the United States and the European Community less the reported output of the Republic of South Africa. These quantities, however, may include significant amounts originating in Southern Rhodesia (see footnotes 3 and 4) rather than in the Territory of South-West Africa. In 1966, total reported production was distributed as follows, in short tons: Amblygonite—30; lepidolite—365; petalite—1,344.

[1] Compiled from import statistics of listed importing countries except where otherwise noted. Conversions to lithium content from reported gross weights were accomplished through the use of the following conversion factors: Lithium carbonate—multiply by 0.188; lithium hydroxide—multiply by 0.165; lithium chloride—multiply by 0.164; lithium bromide—multiply by 0.080. It should be noted that most of the reporting countries provide data for a basket category of "lithium oxide and hydroxide"; this has been assumed to be largely if not entirely the monohydrate of lithium hydroxide ($LiOH.H_2O$) and the factor used for converting gross weight of material so reported to lithium content is based on this assumption.

[2] Source: West German official export statistics because imports of this commodity by this country are not reported separately.

[3] Less than ½ unit.

[4] Source publication reports import of lithium bromide and potassium bromide as a single figure; entry here is an estimate based on the assumption that half of the total was lithium bromide.

[5] Source: France official export statistics because imports of this commodity for this country are not reported separately.

[6] Derived by subtracting reported receipts by listed importing countries from total recorded West German exports.

[7] Totals of listed figures except where otherwise indicated.

[8] Recorded total West German exports.

[1] Compiled from import statistics of listed recipient countries.

[2] Data may include minor quantities of material other than lithium minerals.

[3] Included with imports from the Netherlands.

France.—France imported a total of 184 short tons of lithium equivalent as chemicals and metal, primarily from the United States, West Germany, and the U.S.S.R., in order of volume; the total was virtually unchanged from that of 1973. Approximately 5,000 tons of lithium-mineral concentrate, twice as much as in 1973, was imported, primarily from the Republic of South Africa and Mozambique, but including 500 tons from the United States. Rhône-Poulenc produced lithium compounds, mainly hydroxide, for grease manufacturing. Lithium chemical exports, mainly hydroxide, totaled 20 tons of lithium equivalent, mainly to West Germany.

Germany, West.—As Europe's largest producer of secondary lithium salts, West Germany imported a total of 476 short tons of lithium equivalent, mainly as lithium carbonate and lithium hydroxide, primarily from the United States and the U.S.S.R. Imports were 28% less than 1973. The main reduction was in receipts from the U.S.S.R. Approximately 5,000 tons of lithium mineral concentrate was imported in 1974, about 20% less than in 1973; the principal supplier was South Africa, but 600 tons of spodumene concentrate was imported from the United States. Metallgesellschaft AG at Langelsheim produced lithium hydroxide, butyllithium, lithium halide and lithium metal, using lithium carbonate as the major feedstock. A total of 238 tons of lithium equivalent was exported in lithium chemicals, a 31% reduction from 1973. Twenty short tons of lithium metal was exported, primarily to Switzerland.

Japan.—A total of 686 tons of lithium equivalent as chemicals and metal was imported primarily from the United States and the U.S.S.R.; this represented a 9% increase over 1973. A primary use of these chemicals was in the manufacture of lithium bromide for adsorption air conditioning, demand for which was about 3,000 tons in 1974 and a 50% rise in demand was estimated for 1975. Honjo Chemical Co., the largest Japanese manufacturer of lithium bromide and other lithium chemicals, used 1,100 tons of lithium carbonate to manufacture lithium bromide in 1973. Japan Lithium Co. announced plans to build a 1,500-ton lithium bromide plant by August 1975. Use of lithium carbonate in aluminum cells has not been extensive, only a few hundred tons per year. Lithium chemicals were also used in the manufacture of ceramics, greases, and fluxes.

Mozambique.—Approximately 14,000 short tons of lithium mineral concentrate was shipped to Western Europe, primarily Belgium-Luxembourg and the Netherlands, representing a 23% reduction from that of 1973.

South Africa, Republic of, and Territory of South-West Africa.—The annual capacity of southern Africa's only two large operating mines, Helicon and Rubicon, located southeast of Karibib, and owned by S.W.A. Lithium Mines (Pty.) Ltd., a West German-controlled firm, was estimated to be 11,000 short tons of lepidolite concentrate and 2,800 short tons of petalite concentrate. The working life of these mines was determined to be 20 years. Production figures were not available. Exports of high-grade petalite to Europe remained high. A total of approximately 7,000 short tons of mineral concentrate was exported to Western Europe, primarily to West Germany and France, representing a 7% decrease below that of 1973.

Central Economy Countries.—The U.S.S.R. produced lithium carbonate and hydroxide from spodumene ore. Production figures were not available. The U.S.S.R. was the only major producer of lithium chemicals and metal from ore other than the United States. Exports, measured by trading partner receipts, primarily lithium carbonate with the balance mainly lithium hydroxide, had risen steadily from 260 tons lithium content in 1968 to 646 tons in 1973 but dropped to 452 tons in 1974. All exported lithium hydroxide was reported to be void of Li_6 isotope. An upturn in lithium bromide demand was reported for domestic air conditioning.

The People's Republic of China was reported by the Canadian Mineral Resources Branch in 1973 to have produced 300 tons lithium equivalent of lithium products in 1972.

Other Countries.—Manufacture and use of lithium chemicals continued on a small scale in Italy, Belgium-Luxembourg, and the Netherlands, in order of importance, using imported lithium carbonate and hydroxide and some lithium mineral concentrate as feedstock. Italy imported 73 short tons of lithium equivalent as chemicals and metal, 39% less than in 1973, primarily from West Germany. Italy exported approximately 10,000 tons of lithium mineral concentrate to Israel in 1974. Belgium-Luxembourg imported 52 tons of lithium equivalent as chemicals, about the same as in 1973, and 8,000 tons of lithium mineral concentrate, primarily from Mozambique, about the same as in 1973. The Netherlands imported 25 tons of lithium equivalent as chemicals primarily from West Germany. In addition, approximately 5,000 tons of lithium mineral concentrate was imported mainly from Mozambique, a 56% decrease from 1973. Approximately 1,200 tons of lithium minerals was exported by the Netherlands, primarily to France, Belgium-Luxembourg and West Germany. Production and trade data on the United Kingdom were not available, but over 200 tons total of lithium equivalent as chemicals was reportedly imported in 1973.

World Reserves.—World reserves were estimated to contain 744,000 short tons of lithium; of this, 327,000 tons are located in the United States, 200,000 tons in the U.S.S.R., 100,000 tons each in Africa and Canada, and 17,000 tons in other countries. World reserves were in pegmatite dikes containing 0.5% to 2% lithium and in surface and underground brines. World resources were estimated to contain in excess of 10 million tons of lithium. Although the United States has nearly one-half of the world's known reserves, it probably has less than 20% of the world's identified resources.

Technology.—Development work on rechargeable lithium batteries for electric vehicle surface propulsion and for electrical energy storage in stationary systems for peak-load use continued but at a less accelerated rate. High corrosivity of molten lithium metal at high cell operating temperatures, typically 600° C, was a major problem. Development of lithium alloys, such as lithium-aluminum, partially alleviated this problem in 1974, and a rechargeable lithium-sulfur cell was operated for 1,000 hours at Argonne National Laboratories[5] without damage to a boron-nitride fabric separator. An engineering analysis by Lawrence Livermore Laboratory[6] of Lockheed's lithium-water-air battery recommended further studies to lower the regeneration cost of lithium metal.

---

[5] Chemical & Engineering News. Coal, Biochemistry in Argonnes Wider Focus. V. 52, No. 31, Aug. 5, 1974, pp. 18–21.

MEERSCHAUM[7]

Crude meerschaum was not imported by the United States for the second consecutive year. However, imports of crude meerschaum were expected to be received from Turkey and Somalia in early 1975. Turkey and Somalia have been the principal sources for the past 5 years.

QUARTZ CRYSTAL[8]

ELECTRONIC-GRADE

Production of cultured quartz crystal in 1974 reached record levels by posting a 72% increase over that of 1973 to 528,664 pounds. Cultured quartz consumption exceeded that of natural quartz for the fourth consecutive year. Consumption of both forms of quartz crystal increased. Imports of natural quartz crystal and exports of cultured quartz crystal also were up. Exports of natural quartz were down 81% in quantity in 1974. Production of finished piezoelectric units increased significantly to 35,541,110 units.

Legislation and Government Programs.—The stockpile objective for electronic-grade quartz crystal remained at 209,000 pounds. Continued sales of excess quartz crystal by the General Services Administration led to a decline in the Defense Materials Inventory from 4.05 million pounds of stockpile-grade material at the end of 1973 to 3.82 million pounds at the end of 1974. The non-stockpile-grade quartz inventory declined from 175,096 pounds in 1973 to 4,121 pounds at the end of 1974.

Domestic Production.—There was no reported domestic production of natural electronic-grade quartz crystal during 1974. Seven companies reported production of cultured quartz for use by the quartz crystal cutting industry. These companies were P. R. Hoffman, Carlisle, Pa.; Motorola, Inc., Chicago, Ill.; Bliley Electric Co., Cortland, Ohio; Sawyer Research Products, Inc., Eastlake, Ohio; Thermodynamics Corp., Shawnee Mission, Kans.; Western Electric Co., Inc., North Andover, Mass.; and Electro Dynamics Corp., Shawnee Mission, Kans. Electro Dynamics became the seventh firm to commercially produce cultured quartz and the first to start production since 1970.

Cultured quartz production increased 72% from the revised reported production in 1973 of 306,578 pounds to 528,664 pounds in 1974. The increased production was the result of capacity expansion programs at Thermodynamics and Sawyer Research. Thermodynamics' program led to a more than doubling of capacity for growth of cultured quartz. Additionally, Thermodynamics added a complete facility to process its own cultured quartz. Sawyer Research completed installation of additional crystal growing units, which resulted in an increase of its productive capacity by about one-third.

Consumption and Uses.—Consumption of raw (uncut natural or cultured) quartz crystal climbed to 284,982 pounds, the highest total since 1967. Consumption of natural quartz crystal increased 23% from 99,395 pounds in 1973 to 121,856 pounds in 1974. Cultured quartz consumption exceeded that of natural quartz for the fourth consecutive year. Consumption of cultured quartz increased 9% from 149,534 pounds in 1973 to 163,126 in 1974. The number of finished crystal units fabricated from both forms of raw quartz increased 32% to 35,541,110 units in 1974.

The 1973 production/consumption data were derived from reports received from 35 crystal cutting operations in 14 States. Finished piezoelectric units were produced by 27 of the cutters; the remainder produced only semifinished blanks. Of these, 2 companies consumed natural quartz only, 20 cut cultured quartz only, and 13 cut both natural and cultured quartz.

[6] O'Connell, L. G., B. Rubin, E. Behrin, I. Y. Borg, J. F. Cooper, and H. J. Weisner. The Lithium-Water-Air Battery: A New Concept for Automotive Propulsion. Lawrence Livermore Laboratory, UCRL-51811, May 1, 1975, 36 pp.

[7] Prepared by A. C. Meisinger, industry economist.

[8] Prepared by Stanley Haines, physical scientist.

Seventeen consumers in four States accounted for 85% of the raw quartz crystal consumed in 1974. Pennsylvania was the leading quartz crystal consuming State with over 38% of the total followed by Kansas, Illinois, and Massachusetts.

Piezoelectric units were manufactured by 44 producers in 18 States. Seventeen of these producers worked from partially processed quartz crystal blanks and consumed no raw quartz. Seventeen plants in five States, Kansas, Florida, Pennsylvania, Illinois, and Massachusetts, supplied over three-fourths of the total output of finished crystal units. Oscillator plates comprised 75% of production. The remainder was used for filter plates, telephone resonator plates, and other items.

McCoy Electronics Co. announced that it had purchased the crystal processing equipment from the Collins Radio Co. plant in Newport Beach, Calif. The equipment is being used in the Mt. Holly Springs, Pa., plant and also in the new plant in Mercersburg, Pa.

Stocks.—Total stocks of raw quartz crystal (cultured and natural) increased 124% from 114,205 pounds in 1973 to 256,373 in 1974. Of this total, 174,998 pounds was natural quartz, and 81,375 pounds was cultured quartz.

Foreign Trade.—United States exports of natural quartz crystal decreased 19% from 205,420 pounds in 1973 to 165,837 pounds in 1974. Exports of cultured quartz increased 62% from 82,241 pounds in 1973 to 133,035 pounds in 1974. The average price of natural quartz exported was $9.84 per pound; that of cultured quartz was $20.78 per pound.

Imports of raw natural quartz crystal, valued at more than $0.50 per pound, increased 274% in quantity to 388,677 pounds and 300% in value to $367,943 in 1974. Quartz imported in the over $0.50 per pound category has in the past been reported as electronic and optical-grade quartz crystal. However, as a result of price increases for Brazilian lasca, the nonelectronic-grade quartz used to grow cultured quartz, almost all quartz imported into the United States after September 26, 1974, was valued at over $0.50 per pound. This effectively eliminated the dividing line in trade data between electronic and optical-grade quartz crystal, and lasca. The 389,000 pounds listed in the table as imports of natural quartz crystal is partially electronic-grade quartz and partially the lower quality lasca. Brazil supplied 89% of the quartz crystal in this category. The remainder was supplied by West Germany, the United Kingdom, Israel, Canada, and Venezuela.

Imports of quartz valued at under $0.50 per pound totaled 1,343,236 pounds, valued at $256,405. This quartz was used to manufacture fused quartz and as a nutrient material in the production of cultured quartz. Brazil provided all of the material imported in this category.

World Review.—*Brazil.*—On September 15, 1974, Brazil suspended exports of all quartz materials due to what was believed to be unrealistic pricing and classification procedures in Brazil. The suspension was lifted on September 26, 1974, with the announcement of an export limit of 662 short tons for lasca through December 1974. A floor price of $3.50 per kilogram was set for the lasca. Brazil announced an export quota for 1975 of 3,859 short tons of lasca. The floor prices announced for 1975 were to be $6 per kilogram of first-grade lasca; $3.50 per kilogram of second-grade lasca; and $1.60 per kilogram of third-grade lasca.

In 1974, lasca exports totaled 7,619 tons valued at $6.1 million. Piezoelectric-grade exports totaled 38 tons valued at $116,000.

Technology.—An experiment was performed by astronauts on Skylab 3 and 4 to see what effects zero gravity would have on the growth of crystals. The two major results of the experiments, which grew crystals of germanium and selenium, were higher quality crystals than earth-grown varieties and a faster growth rate. If such experiments could be expanded to include quartz, a new generation of higher quality quartz crystal could evolve.[9]

STAUROLITE [10]

Staurolite is a complex iron-aluminum silicate of uncertain and most likely variable composition. The mineral occurs as opaque crystals that are reddish-brown to black, have a specific gravity of 3.65 to 3.77, and fall between quartz and topaz in hardness (7 to 8 on Moh's scale). Aside from a small rock-shop trade in cruciform-twinned crystals from some deposits that are sold as curiosities or amulets ("fairy crosses"), all the staurolite produced commercially in the United States is a byproduct obtained by high-intensity magnetic separation of a heavy-mineral mixture recovered by E. I. du Pont de Nemours & Co., Inc., from beach sand in a glacial age deposit in Clay County, Fla.

Formerly the staurolite concentrate was used only as an ingredient in portland cement mixtures, but more recently this product (which may contain minor proportions of five or six other minerals and averages approximately 45% Al_2O_3, 15% Fe_2O_3, and 30% SiO_2) is being marketed by du Pont under two trade names, "Starblast" for use as a sandblast abrasive, and "Biasil" for mixing with bentonite and other substances to prepare special-purpose foundry sand.

Quantitative production data are not released for publication, but the 1974 output of staurolite was 12% greater than that of 1973 while shipments increased 11% in tonnage and 28% in total value.

STRONTIUM [11]

Domestic consumption of strontium on a strontium carbonate basis was estimated at 25,000 tons in 1974, representing a 24% decrease from that of the previous year. Imports of strontium minerals increased sharply over 1973 to 38,431 tons. Imports of strontium chemicals, primarily from Canada, also increased 47% compared with those in 1973.

Legislation and Government Programs.—The Government sold 4,052 tons of stockpile-grade celestite during 1974. Government stockpiles contained 14,408 tons of non-stockpile grade at yearend.[12]

Domestic Production.—Strontium minerals have not been produced commercially in the United States since 1959. However, a number of firms produced strontium compounds from imported celestite, a strontium sulfate.

Table 10.—Major producers of strontium compounds, 1974

Company	Location	Compounds
Atomergic Chemetals Co	Carle Place, N.Y	Various compounds.
J. T. Baker Chemical Co	Phillipsburg, N.J	Do.
Barium & Chemicals, Inc	Steubenville, Ohio	Do.
Chemical Products Corp	Cartersville, Ga	Carbonate.
E. I. du Pont de Nemours & Co., Inc	Grasselli, N.J	Nitrate.
FMC Corp	Modesto, Calif	Carbonate, hydrate, nitrate.
Hercules Inc	Glens Falls, N.Y	Chromate.
King Laboratories, Inc	Syracuse, N.Y	Metal alloys.
Mallinckrodt Chemical Works	St. Louis, Mo	Various compounds.
Mineral Pigments Corp	Beltsville, Md	Chromate, molybdate.
NL Industries, Inc., Tam Div	South Amboy, N.J	Titanates.

Prices.—At yearend, prices quoted in the Chemical Marketing Reporter were as follows: Strontium carbonate—technical, bags, carlots, works, 13 to 21 cents per pound; strontium nitrate—bags, carlots, works, $15 per 100 pounds, unchanged from the previous year. Prices for strontium minerals are usually determined by direct negotiation between buyer and seller and are seldom published. The average value of imported strontium minerals at foreign ports was $30 per short ton.

Foreign Trade.—Imports of strontium minerals totaled 38,431 tons, a 42% increase over those of 1973. The material was imported from Mexico and Spain. Imports of strontium compounds increased 47% over those of 1973 with 94% of the material coming from Canada. Quantitative data on U.S. exports of strontium compounds were not available.

Consumption and Uses.—Domestic consumption of celesite in the manufacture of various strontium chemicals continued its decline from the 1971 high as carbonate from Canada entered the market in larger quantities. Quantitative information concerning consumption is incomplete; however, one leading company reported a decrease in consumption in 1974 from that of 1973. Sales of domestically produced strontium carbonate to manufacturers of glass for color television picture tubes again declined. Celestite consumption in the manufacture of chemicals for pyrotechnics appeared to have been stabilized.

Miscellaneous applications for strontium compounds included ferrites, greases, ceramics, plastics, toothpaste, pharmaceuticals, paint, electronic components, welding fluxes, and high-purity zinc. Small quantities of strontium metal were used by research companies.

e Estimate. p Preliminary.

[1] In addition to the countries listed, West Germany, Poland, and the U.S.S.R. produce strontium minerals, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[2] Year beginning March 21 of that stated.

World Review.—*Canada.*—Kaiser Strontium Products Ltd. marketed strontium chemicals worldwide from its plant at Point Edward, Cape Breton Island, Nova Scotia. Technical problems that hampered the commercial-scale production of glass-grade strontium carbonate appeared to be under control.

Technology.—An Al-16% Si-10% strontium master alloy for modifying hypoeutectic aluminum-silicon alloys, which offers substantial cost advantages over the conventional sodium method, was marketed. Addition of the strontium master alloy was convenient and recovery of the strontium was satisfactory. Fume generation and uncertain recovery, major problems associated with sodium modification, were eliminated. Additions of the new master alloy resulted in 20% to 100% increases in elongation and significant increases in tensile and yield strengths of cast and machined test bars.[13]

WOLLASTONITE[14]

Wollastonite is a natural calcium metasilicate, usually white or light-colored and sometimes acicular to silky fibrous in structure, with a specific gravity of 2.87 to 3.09 and a Moh's hardness of 4½ to 5. The mineral, useful as a ceramic raw material, as a filler for plastics and asphalt products, as a pigment and extender for paints, and in miscellaneous minor applications, was mined in the United States in 1974 by Interpace Corp. at an underground operation in Essex County, N.Y. Specific output data were not released for publication, but the tonnage produced in 1974 was 2% less than that in 1973, while the reported total value was higher. Of interest in this regard was a communication published in an industrial magazine[15] implying that current domestic production of wollastonite is in the neighborhood of 50,000 tons per year. The same letter stated that wollastonite can serve in certain applications as a satisfactory substitute for asbestos, obviating exposure of the involved workers to the health hazards of that material.

Chemical Marketing Reporter, December 30, 1974, quoted $43.80 per ton as the price for wollastonite, fine paint grade, bagged, in carload lots, f.o.b. works. The price range quoted in the December 1974 issue of Industrial Minerals (London) for wollastonite (imported ground, bagged, CIF main European port) was approximately equivalent to from $76 to $94 per ton.

Production of wollastonite outside the United States in 1974 was reported at Lappeenranta, Finland (flotation concentrate said to amount to about 7,000 tons), and from a newly discovered deposit near Sirohi, Rājasthān, India (quantity not specified).[16]
